Call No.

Acc. No 18910

Indian Agricultural Research Institute (Pusa)
LIBRARY, NEW DELHI-110012

This book can be issued on or after ____________

Return Date	Return Date

[illegible] 28/1939.

INDEX

NAME INDEX

18910

Abbe (Cleveland), (1838–1916) work of, 946

Abbot (Dr C G), and W H Hoover Precision Methods of Measuring Stellar Radiation 1007

Abel (Prof J J), [obituary article], 242

Abbott (Capt C A) gift to the Iron and Steel Institute for a prize, 714

Abraham (H), Asphalts and Allied Substances their Occurrence, Modes of Production Uses in the Arts and Methods of Testing Fourth edition (*Review*) 654

Ackerley (Archdeacon) The Gypsy Problem, 246

Ackermann (A S E) A Curious Atmospheric Phenomenon 482

Ackermann (W), [Prof D Hilbert and] Grundzüge der theoretische Logik (*Review*), 413

Ackers (C P), Practical British Forestry (*Review*) 650

Adam (Ann B), [L. C Comrie and] Female Reproductive System and Corpora Lutea of the False Killer Whale *Pseudorca crassidens* Owen, 305

[illegible]heim (Prof R), elected a member of the German Academy of Natural Science at Halle 1115

[illegible], and L S Price A Higher School [illegible]istry (*Review*) 733

[illegible] on in the Central Nervous [illegible]

[illegible] member of the Prussian Academy of Sciences, [illegible]

[illegible]mann (Prof H W), and S Thorarinsson Advance and Retreat of Glaciers, 298

[illegible] (N), [Dr B P Pal and], Hybrid Vigour in Wheat 1002

Albert (Dr A), and Dorothy K Large, Preparation of 2 : 8 Diamino Acridine, 435

Alexander (Prof S), [death] 504, [obituary article] 603

Alexandre de Villedieu, avec traduction et commentaire par W E Van Wijk Le Nombre d Or (*Review*) 451

Alford (Miss Violet) Pyrenean Festivals Calendar Customs, Music and Magic Drama and Dance (*Review*), 775

[illegible] (H) Variation of Cosmic Rays with Time, 622

[illegible]on (Very Rev Dr C A) elected president of the University of Durham Philosophical Society 991

[illegible] (Dr Clifford), Psychiatry from the Behaviourist Point of View (*Review*), 53

[illegible] (E P), awarded the Chester Beatty scholarship in Radiology of London University, 846

All[illegible] (Dr F W), [Prof C L A Schmidt and] Fundamentals of Biochemistry, with Laboratory Experiments (*Review*) 1017

[illegible] (Prof H S), Time and Probability, 354

[illegible] (Dr J F), Low Temperature Physics 522, and [illegible] D Misener, Flow Phenomena in Liquid Helium II, 643

[illegible] (R G D), Mathematical Analysis for Economists (*Review*), 6

[illegible] Jun (E. P), Development of the Vertebrate Head, [illegible]64

[illegible] L), Iron Deficiency in Pregnant Rats, 1164

[illegible]ltnes (L. A.), [L. Hackspill and], Action of Caesium on Carbon Monoxide, 266

[illegible] S. W.), Migration of Man Past, Present and Future (*Review*), 271

[illegible]es (L. W.), Capture of Orbital Electrons by [illegible]

Amat (M) [J Duclaux and] Ultra filters of Graduated Porosity 87

Aminal (Dr F K J) A *Saccharum Zea* Cross 618

Anderson (Dr C D) and Dr S H Neddermeyer, Mesotron (Intermediate Particle) as a Name for the New Particles of Intermediate Mass 878

Anderson (E M) Dynamics of Sheet Intrusion with some Considerations on Faulting 128 Seismological Data and Volcanicity 1043

Andersson (K) [Prof The Svedberg and], Ultracentrifugal Examination of Serum from the Lower Classes of Vertebrates 147

Andrade (Prof E N da C) Science in the Seventeenth Century 19

Antevs (E) Rainfall and Tree Growth in the Great Basin (*Review*) 234

Aoki (H) [Prof S Kikuchi and] The Electron Neutron Interaction 832

Appell (Prof P) *Analyse des courbes surfaces et fonctions usuelles intégrales simples* Tome I Cinq edition entierement refondue par Prof G Valiron (*Review*) 1139

Appleton (Prof A B) Prof W J Hamilton and Dr I C C Tchaperoff Surface and Radiological Anatomy for Students and General Practitioners (*Review*) 555

Appleton (Prof E V) Radio Transmission and Solar Activity 499 and K Weekes Tides in the Upper Atmosphere 71

Appleyard (Dr E T S) and A D Misener Superconductivity of Thin Films of Mercury 474

Appleyard (R) Fundamental Physical Structure 537 A Comprehensive Fundamental Electrical Formula 1163

Arber (Dr Agnes) Herbals their Origin and Evolution A Chapter in the History of Botany 1470 1670 New Edition (*Review*) 272

Archbold (H K) Role of Fructosans in Carbohydrate Metabolism 1083

Archey (G) Chilopoda of New Zealand, 41

Argand (Prof E) elected a foreign fellow of the Geological Society of London 1033

Arley (N) and Dr W Heitler Neutral Particles in Cosmic Radiation 158

Armstrong (Dr E F) Shale Oil Industry 639

Arnold (Dr G) National Museum of Southern Rhodesia 505

Arnot (Dr F L) Band Spectrum of Helium, 536

Arthur (W) [Prof T M MacRobert and], Trigonometry Parts 2 3 and 4 (*Review*), 663, Trigonometry Part I Intermediate Trigonometry (*Review*) 1142

Ashbridge (Sir Noel) Television (Thomas Hawksley lecture), 923

Ashby (Prof E), Practical Genetics (*Review*), 933

Ashley Montagu (Prof M F) Trimethylamine in Menstruous Women, 1121

Aspdin (Joseph), memorial to work of, 1031

Astbury (Dr W T), Florence O Bell, Prof E Gorter and Dr J Van Ormondt, Optical and X Ray Examination and Direct Measurement of Built up Protein F[illegible]

[illegible]

18910

Aten, jun (A H W) and Prof G Hevesy Formation of Milk 111 Diffusion of Phosphate Ions into Blood Corpuscles 871 Fate of the Sulphate Radical in the Animal Body 952
Atkins (Dr W R G) Modified Use of the Hæmocytometer for Counting Sparse Fields, 265
Auger (P) Study of large Cosmic Ray Showers at an altitude of 3 500 m 1048
Austen (late Major F E) Bombyliidæ of Palestine (*Review*) 596
Auwers (Arthur) centenary of the birth of work of 467
v Auwers (Dr O) Magnetische und elektrische Eigenschaften des Eisens und seiner Legierungen (*Review*) 1015
Ayyangar (R) and others Genetics of Millet and *Sorghum* 22 Morphology of *Sorghum* species 1083

Babcock (E B) and G L Stebbins jun The Genus Youngia (*Review*) 1058
Bacharach (A L) Biological Assay of Vitamin E 35 Dosage and Response in Vitamin E Treatment 675
Baden Powell (D F W) [J Reid Moir and] A Palæolithic Industry from the Cromer District 912
Baekeland (Dr L A) Science and Industry (Messel memorial lecture) 203
Bagnold (Major R A) Grain Structure of Sand Dunes and its Relation to their Water Content 403
Bahl (Dr K N) granted a doctorate by Oxford University 880
Baildon (F) appointed assistant lecturer in mechanical engineering in Sheffield University 765
Bailey (C R) conferment upon of the title of reader by London University 1170
Bailey (Prof E B) International Co operation in Geology (*Review*) 972
Bailey (J F) [death] 906
Bailey (S H) International Studies in Modern Education (*Review*) 1
Bailey (Prof V A) Generation of Auroras by Means of Radio Waves 613 and Prof J M Somervill Ionosphere Radio Waves 1126
Baird (J L) Development of Television 887
Bakken (Ruth) and Ellen Gleditsch Lead Uranium Thorium Ratio in Cleveite 485
Balozet (L) Adsorption of the Virus of Sheep Rot by Aluminium Hydroxide 627
Banerjee (S) [Prof K S Krishnan and] Magnetic Anisotropies and the Valencies of Paramagnetic Atoms in Crystals 717
Banga (I) F Philippot and Prof A Szent Gyorgyi Dioxymaleic Acid Oxidase 874
Bannister (F A) appointed deputy keeper in the Mineralogy Department of the British Museum (Natural History) 1155
Barber (D R) Sky Darkening Associated with a Severe Thunderstorm 359
Barber (Dr M A) presented with the Mary Kingsley medal 988
Barclay (R S) and Dr W O Kermack Diagonal Law of Birthrate Decline 41
Barclay (W R) [obituary article] 562
Barcroft (Sir Joseph) appointed a member of the Agricultural Research Council, 32
Barger (E) Results of the recent Archæological Expedition to Swat and Afghanistan in relation to the Present Position of Indian Studies in this Country 1046
Barger (Prof G) awarded the Davy medal of the Royal Society 865 presented with the Davy medal of the Society, work of, 1045
[illegible]
…ment 836
…F), appointed an indu… [illegible]
[illegible]
Barnes (Dr B) [Dame H C I Gwynne Vaugha The Structure and Development of the Second edition (*Review*) 55
Barnett (Dr E de Barry) appointed head of the co chemistry departments of the Sir John Cass Te Institute 473
Barnwell (Capt F S) [death] 282
Baron (J) and P Laffitte Inflammation of I Propyl Ether 47
Barr (Sir James) [death] 986
Barrett (A M) appointed demonstrator in pathol Cambridge University 926
Barrett (Sir James) Reminiscences of 244
Barrie (Miss M M O) Vitamin F Deficiency Suckling Rat 799
Barrillon (Prof E G) elected a member of the of geography and navigation of the Paris Ac of Sciences 206
Barrow (R F) Ultra Violet Band System in Monoselenide 434 Ultra Violet Band Syst Silicon Monotelluride 536
Bartlett (Prof F C) Prof William McDougall 11
Barua (P K) [W Wight and] Toxicity of Mercury to Insects 754
Barve (P M) [B N Desai Y S Paranjpe and] C Vanadium Pentoxide 1091
Bashford (Sir Henry) appointed a member of the Ind Health Research Board of the Medical Re Council 714
Bastedo (W A) N R Trenner and T J Webb I tion of Vitamin B 1084
Basu (Capt R N) Blood Groups among the Khas
Bateman (H) Rayleigh Waves 587
Bateman (J B) and Dr I A Chambers Rig Protein Films and the Properties of the For Curves 1158
Bateson (R G) Timber Drying and the Behavi Seasoned Timber in Use (*Review*) 231 Hum British Isles 1123
Bauer (D J) re elected Michael Foster stude physiology in Cambridge University 264 ele fellow of Trinity College Cambridge 765
Baumgardt (L) Determination of the Adiabatic I of Elasticity 586
Bawden (F C) and N W Pirie Aggregation of P Tobacco Mosaic Virus 842
Baxenden (J) Electric Lines of Force 165
Bay (Prof Z) appointed professor of atomic phy the Institute for Atomic Physics of the Hungarian University 352
Beadnell (Surg Admiral C M) Dictionary of Sci Terms as Used in the Various Sciences (*Review*
Beaglehole (Ernest and Pearl) People and Cult Pukapuka 215
Beall (D) and Prof T Reichstein Isolation of gesterone and Allopregnanolone from the A 479
Bear (Dr I E) Theory and Practice in the U Fertilizers Second edition (*Review*) 658
Beattie (Dr J) [Prof W Le Gros Clark Dr G Ri N M Dott and] The Hypothalamus Morphol Functional Clinical and Surgical Aspects (*Revie*
Beck (Conrad) The Microscope Theory and Pr (*Review*) 664
Beck (G), and W Nowacki Compounds of Di Europium 579
Becking (Prof L G M Baas) [H Veendorp and] 1937 Hortus Academicus Lugduno Batavus Development of the Gardens of Leyden Univ (*Review*), 1013, [H. W [illegible] between Inter [illegible]
[illegible]

6793

Bell (Florence O) [Dr W T Astbury Prof E Gorter Dr J Van Ormondt and] Optical and X Ray Examination and Direct Measurement of Built-up Protein Films 33

Bell (Prof R J T) Co ordinate Solid Geometry (*Review*) 895

Benham (W E) Waves Associated with Moving Corpuscles 160

Benjamin (Prof A C) An Introduction to the Philosophy of Science (*Review*) 413

Benndorf (H) and E Rumpf Badly Conducting Surface Layers on apparently Clean Metals and their effect on the Operation of Sensitive Electrometers 1092

Bennett (C W) and H E Wallace Insect Vectors of Beet Curly top Virus, 215

Bennett (Prof G M) admitted a fellow of Queen Mary College 1069 and Dr P V Youle By products in Aromatic Nitration 356

Benz (F) [Dr M Hartmann and] Sugar Content of the Hormones of the Pituitary Anterior Lobe and of the Gonadotropic Hormone from Pregnancy Urine 115

Berg (W F) and K Mendelssohn Photographic Sensitivity at Low Temperatures 1126

Bergel (Dr F) A Jacob Dr A R Todd and T S Work Vitamin F Synthesis of α Tocopherol 36

Berger (Prof C A) Cytology of Metamorphosis in the Culicinæ 117

Bergh (F) Dr O M Henriques and C G Wolffbrandt Prague Sero Reactions for Cancer 212

Bergmann (Dr F) and Prof R Samuel Mechanism of the Primary Photodissociation Processes of Organic Molecules 919 and Y Hirshberg Photochemistry of Δ^4 Cholestenone 1037

Bergmann (L) Experiments with Supersonics 263

Bergstrand (Prof C O F) elected a *correspondant* of the Paris Academy of Sciences 473

Beringer (Dr C C) Geologisches Worterbuch Erklärung der geologischen Fachausdrücke (*Review*) 662

Bernal (Prof J D) I Fankuchen and D P Riley Structure of the Crystals of Tomato Bushy Stunt Virus Preparations 1075

Bernard (R) Enhancement of the Sodium *D* Lines in the Twilight Sky Light 164

Bernth (O) [Dr H Dam J Glavind and F Hagens and], Anti Encephalomalacia Activity of *dl* α Tocopherol 1157

Berridge (F R) appointed assistant in research in radiology (diagnostic) in Cambridge University 765

Berry (A J) Qualitative Inorganic Analysis (*Review*) 96

Best (Prof C) Insulin and Diabetes the Present Position (Stephen Paget memorial lecture) 425

Bewley (Dr W F) and J Harnett The Cultivation of Mushrooms Second edition (*Review*) 416

Bews (Prof J W) [death] 986 [obituary article] 1066

Beynon (J H) Prof I M Heilbron and Dr F S Spring Structure of the Triterpenes 434

Beynon (W J G) [R Naismith and] Bright Solar Eruptions and the Ionosphere 250

Billimoria (M C) [Prof W H Pearsall and] Protein Synthesis in Detached Leaves 120

Billson (H G) [death] 865

Binnie (W J E) Science and Engineering in Ancient Times 822

Birch (T T C) New Zealand Forest Fungi 840

Bird (Prof R M) [death] 104

Birket Smith (Dr K) and Dr Frederica de Laguna The Eyak Indians of the Copper River Delta Alaska 839

Birkofer (L) [R Kuhn and] Mechanism of Mutarotation 486

Birse (E A B) [Dr H W Melville and] Photochemistry of Ammonia, 1080

Birt (Col C) bequest to the Royal Society of Medicine 32

[illegible]ch (J), [A Chrétien and] Active Aluminium obtained by Igneous Electrolysis 547

Blackett (Prof P M S) High Altitude Cosmic Radiation, 692; Further evidence for the Radioactive Decay of Mesotrons, 992

Blackman (V H), [H Dickson and] Absorption of Gas Bubbles in Wood Vessels 42

Bland (Dr J O W) [Dr C F Robinow and], Application of the Feulgen Method to the Study of Viruses, 720

Blau (Marietta) Photographic Tracks from Cosmic Rays, 813

Bledisloe (Viscount) elected President of the Museums Association 222

Blinks (L R) and R K Skow Time Course of Photosynthesis as shown by the Glass Electrode with Anomalies in the Acidity Changes Time Course of Photosynthesis as shown by a Rapid Electrode Method for Oxygen 1133

Bloch (Mlle France) Constitution of the Thioacids 180

Blondel (A) [death] 1067

Blumenthal (Prof I M) Distance Geometries 1003

Blumenthal (M) Action of Water Vapour on Amalgamated Aluminium 1049

Bocheński (T A) Fructification Cones of Sigillarians and their mode of Insertion on the Trunks 1049

Boerhaave (Herman) two hundredth anniversary of the death of work of 504

Boettger (F C) A Simple Respirometer for Small Animals 161

Bohr (Prof N) awarded the Copley medal of the Royal Society 8[illegible] presented with the Copley medal of the Royal Society work of 1044 and others Nuclear Physics 520

Bok (Prof B J) Distribution of the Stars in Space 31

Bolam (Dr T R) Physical Chemistry of Textile Materials (*Review*) 94

Bonacina (L C W) Turner s Portrayal of the Weather, 947

Bond (Dr G) Excretion from Leguminous Root Nodules 539

Bone (Prof W A) [obituary article] 62

Bonner (J) and F R Buchman Syntheses carried out *in vivo* by Isolated Pea Roots (1) 1134

Bonser (G M) [Dr J M Robson and] Production of Mammary Carcinomas in Mice of a Susceptible Strain by the Synthetic Œstrogen Triphenyl Ethylene 836

Bordet (Prof J) presented with the Grand Cross of the Legion of Honour 1033

Borer (O) Reclamation of Tidal Lands 366

Boring (E G) H Langfeld, H P Weld and collaborators A Manual of Psychological Experiments (*Review*) 498

Borocco (A) Action of Ultra Violet Rays on Mercury Fulminate 491

Botley (Miss C M) The Air and its Mysteries (*Review*), 375

Bourgeois (R) Daily Exploration of the Atmosphere by *radio sondes* its Development on Land and on Sea, 887

Bourne (Dr G) [Dr S Zuckerman D Lewes and], Cyclical Changes in the Adrenal Glands of Spayed Rats 754

Boutry (Prof G A) Contacts of Science with Social Problems 422

Boutry (G A) and R Zouckermann Use of Dry [Copper-Copper Oxide] Rectifier for the Production of Continuous High Tension [Current] 767

Bowden (Dr F P) award to from the Beilby Memorial Fund work of 1072 and T P Hughes Friction of Clean Metals and the influence of Surface Films 1039

Bowden (Dr S T) Free Radical Terminology, 879 A Modified Phase Rule Equation, 958

Bowen (E J) Fluorescence of Solids, 1081

Bowen (Prof I S) and Dr R Minkowski Effect of Collisions on the Intensities of Nebular Lines 1079

Bower (Prof F O) Sixty Years of Botany in Britain (1875–1935) Impressions of an Eye Witness (*Review*), 51 awarded the Darwin medal of the Royal Society, 865 presented with the Darwin medal of the Royal Society work of 1045

Bowman Manifold (M) and F H Nicoll, Electrolytic Field Plotting Trough for Circularly Symmetric Systems 39

Boycott (Prof A E) [obituary article] 13
Boyd (Dr J D) appointed professor of anatomy at the London Hospital Medical College 46
Boyd (Lt Col J S K) Typhoid Paratyphoid Vaccination in the British Army 361
Bozzano (E) translated by Isabel Emerson Discarnate Influence in Human Life a Review of the Case for Spirit Intervention (*Review*) 376
Bradford (Dr S C) International Federation for Documentation Conference at Oxford and London 678
Bradley (Dr A J) appointed assistant director of research in Crystallography in Cambridge University 46 conferment upon of the degree of M A by Cambridge University 1047
Bradley (W H) and J F Pepper Gas Possibilities in New York State 677
Bragg (Sir William) elected a foreign associate of the Paris Academy of Sciences 110 249 Relation of Science to Industry, 565 re elected president of the Royal Society 906 Molecular Basis of the Strength of Materials (Andrew Laing lecture) 910 Publication of Scientific Research 1028
Bramhall (F H) Alaska Earthquake of July 22 1937 172
Bransby (Dr E R) Relationship between Household Income and Food Expenditure 1162
Braunholtz (Dr W T K) and others Coal Treatment and Utilization 1129
Bray (G R R) Binocular Illusion 959
Bray (R J) awarded a postgraduate studentship of London University 179
Brdička (Dr R) The Polarographic Sero Reaction for Cancer 617
Breuil (Abbé) elected a member of the Académie des Inscriptions et Belles Lettres 244
Brewer (Dr A K) [Dr A Lasnitzki and] Isotopic Constitution of Potassium in Normal and Tumour Tissue 538
Bridges (Dr C H) Future of Genetics 178
Brill (R) Surface Films on Water 262
Brillouin (M) Inevitable Instability of a Heavy Liquid which rotates without Relative Movement with a Solid Nucleus which it surrounds 1009
Brinkman (Dr R) and J H P Jonxis Oxygen Transport with Fully Reduced Arterial Hæmoglobin in the Human Being 115
Broad (Prof C D) Examination of McTaggart s Philosophy Vol 2 Parts 1 and 2 (*Review*) 665 Serialism and Immortality (*Review*) 1052
Brockway (L O) The Fluorine Molecule 260
Broda (Dr E) Limited and Unlimited Swelling of High Molecular Substances 116
Brode (R B) [D R Corson and] Specific Ionization of Cosmic Ray Particles 81
Broersma (G) [J J Broeze H van Driel L A Peletier and] Combustion Pressures in Spark Ignition Engines 798
Broeze (J J) H van Driel L A Peletier and G Broersma Combustion Pressures in Spark Ignition Engines 798
de Broglie (Prince Louis Victor) elected a member of the physics section of the Royal Swedish Academy of Sciences 1033
Broh Kahn (R H) [T L Snyder and] Substitution of Cysteine for Protohæmin as the X Factor for Growth of *H influenzæ* 153
Brohult (S) [Prof The Svedberg and] Splitting of the Hæmocyanin Molecule by Ultra Violet Light 830
Brönsted (Prof J N) translated by R P Bell Physical Chemistry (*Review*) 273
Brooks (Prof F T) appointed a governor of the National Fruit and Cider Institute 127
Brooks (G) Relation between Fluorescence and the Chemical Constitution of Laccol Moreacol and their Derivatives 968
Broom (Dr R) The Pleistocene Anthropoid Apes of South Africa 377 Further Evidence on the Structure of the South African Pleistocene Anthropoids 897 908
Broughton (Margaret Elizabeth) awarded a postgraduate travelling studentship of London University 179
Broughton (G) and R S Hand Viscosity of Clay Suspensions 255
Brown (Prof A R Radcliffe) presented with a Rivers memorial medal of the Royal Anthropological Society 70
Brown (Prof E W) [death] 243
Brown (F) Compilation of Statistics by Trade Associations 679
Brown (Dr G Burniston) A Report on Three Experimental Fire Walks by Ahmed Hussain and others 67
Brown (Prof H A) Radio Frequency Electrical Measurements a Guide for Radio Engineering Laboratory Instruction Second edition (*Review*) 661
Brown (Prof N C) Timber Products and Industries (*Review*) 231
Brown (Prof O E) [Prof M Morris and] Analytic Geometry and Calculus (*Review*) 1018
Brown (Dr W) Hypnosis Suggestibility and Progressive Relaxation 404
Brownlie (D) The Cause of Cancer (*Review*) 8
Brumpt (Prof F) presented with the Mary Kingsley medal 988
Brunel (A) [M Molliard R Échevin and] Nitrogen Composition of Variegated Leaves 1133
Brunt (Prof D) Weather Science for Everybody (*Review*) 734
de Bruyne (Dr N A) The Swelling of Birch Wood 570
Bryant (C L) Modern Methods in School Science (*Review*) 891
Buchanan (Dr R O) conferment upon of the title of reader by London University 1170
Buchanan (Prof S) The Doctrine of Signatures A Defence of Theory in Medicine (*Review*) 976
Buchanan Wollaston (H J) A Useful Statistical Test 160
Buchman (E R) [J Bonner and] Syntheses Carried out *in vitro* by Isolated Pea Roots (1) 1134
Buck (Prof J L) Land Utilization in China 2 Vols and Atlas (*Review*) 454
Buffle (J P) C Jung and P Rossier A Lacustrine Optical Phenomenon Irisation of March 8 1938 628
Buhl (Prof M A) Variables Complexes (*Review*) 1139
Builder (Dr G) and J D Gilchrist Communication Equipment for Vehicles 826
Bullard (Dr E C) and T F Gaskell Seismic Methods in Submarine Geology 916
Bullen (Dr K E) Composition of the Earth at a Depth of 500–700 km 671 Geocentric Distances in Seismology 802
Bulliard (H) I Grundland and A Moussa Detection of the Phosphorus of Supra renal Phosphatides by Radio phosphorus 969
Bullinger (Mlle E) [J Roche and] Phosphatases of the Osseous System of Fishes (Selachians and Teleosteans) 1049
Bulloch (Prof W) The History of Bacteriology (Heath Clark lectures 1936) (*Review*) 771
Burchell (J P T) Prehistoric Pottery in Kent 989
Burgess (Dr R) [L D Galloway and] Applied Mycology and Bacteriology (*Review*) 235
Burke (B S) [H M Teel R Draper and] Vitamin C in Pregnancy and Lactation 1164
Burkitt (M C) International Congress of Anthropological and Ethnological Sciences 363 The Middle Palæolithic 512
Burnop (V C E) awarded a postgraduate studentship of London University 179
Burrow (Dr T) Kymograph Studies of Physiological (Respiratory) Concomitants in Two Types of Attentional Adaptation, 156
Burrows (Rev E) S J [obituary article] 282
Burton (Prof E F) Viscosity of Liquid Helium II 72
Burton (Dr M) Porifera of Krusadai Island 401
Burtt (B D) [obituary article] 199
Burtt (E) Irritant Exudation from a Millipede 796
Butcher (Dr R W) Dr J Longwell and F T K Pentelow Survey of the River Tees Part 3 177
Butler (G C) [Prof G F Marrian and] Chemical Studies on the Adreno Genital Syndrome, 400

Butler (Dr J A V) Complex Osmosis (*Review*) 812
Butterfield (R) [obituary] 986
Buttgenbach (H) Symbolization of Crystalline Forms 627
Buxton (Prof P A) British Mosquitoes (*Review*) 773
Byers (Dr H R) Synoptic and Aeronautical Meteorology (*Review*) 664

Cabannes (Prof J) Prof J Dufay and J Gauzit CH Bands in the Night Sky Spectrum 718 CN Bands in the Night Sky Spectrum 75
Cabrera (B) Influence of Water on the Values of the Magnetic Constants of the Rare Earths 1171
Cahen (R) and Mme Andrée Tronchon Action of Zinc on the Œstrogenic Effects of Folliculine in the Ovariectomized Rat 47
Calder (R M) awarded the Graham scholarship in pathology of London University 1170
Caldwell (Dr J) Stripe Disease of Narcissus 441
Califano (Prof L) and D Kertesz Tyrosinase and Catechol Oxidase 1036
Callender (Sir Thomas) [death] 1028 [obituary article] 1066
Calmette (Dr A) monument to at Nice 70
Cameron (Prof A T) A Text book of Biochemistry for Students of Medicine and Science Fifth edition (*Review*) 977
Campbell (A H) A Lignicolous Fungus 1124 and A E Vines Leaf Abscission in Healthy and Diseased Leaves of *Picea* 881
Campbell (Dr D H) Californian Hepatics 1124
Campbell (Dr G A) The Collected Papers of (*Review*) 591
Campbell (J A) [A W Henry and] Soil Organisms and Seed borne Pathogens 961
Campbell (Sir Malcolm) Water Speed Record 568
Campbell (Dr N R) Scientific Pursuit and Personality (*Review*) 690
Campbell (N R) Prof F C Dodds and W Lawson Œstrogenic Activity of Anol A Highly Active Phenol isolated from the By Products 1121
Campbell (W E) and U B Thomas Films on Freshly Abraded Copper Surfaces 253
Campbell (W G) Prof F I Hirst and C T Young Estimation of Uronic Anhydride Residues in Polysaccharides 912
Campbell (Dr W W) [obituary article] 102
Carathéodory (Prof C) Geometrische Optik (*Review*) 135
Carpenter (Dr C C) [death] 704 [obituary articles] 636 904
Carrillo (A) Mexico's Resources for Livelihood 1008
Carver (J C) [Dr A S Russell and] Reduction of Ions of Nickel Cobalt Iron and other Metals by Zinc Amalgam 210
Casimir (Dr H B G) and others Low Temperature Physics 522
Caspersson (Prof T) and Dr J Schultz Nucleic Acid Metabolism of the Chromosomes in Relation to Gene Reproduction 294
Castellani (Sir Aldo) Climate and Acclimatization Second edition (*Review*) 663
Castelnuovo (Prof G) Memorie scelte (*Review*) 1016
Catanei (A) [L Parrot and] Factors in the Occurrence of Epidemics of Paludism in Algeria 1009
Cathcart (Prof E P) Physical Fitness 237
Caton Thompson (Miss G) Geology and Archæology of the Hadhramaut South West Arabia Preliminary Notes on the Lord Wakefield Expedition 139 Archæological Investigations in the Hadhramaut 867
Cavanaugh (Prof G W) [death] 282
Cave (Capt C J P) Smoke like Swarms of the Harlequin Fly 505 Dry Crossing of the Nile 576
Cawston (Dr F G) Effects of Injury on the Teeth of Selachii 118 Succession of Teeth in Molluscs 627 Normal Dentition of Sharks 878
Cayeux (L) Problem of the Ancient Port of Tyre Studied in the Light of Petrography 1048
Cayley (Miss D M) The Cultivated Mushroom 485
Céline (L F), translated by R A Parker Mea Culpa and the Life and Work of Semmelweis (*Review*) 316
Cesàro (G) and J Mélon Crystalline Form of Acmite 787 The Plane Method for the Identification of Crystallizable Substances 887
Chadwick (Prof J) The Cyclotron and its Applications 630
Chalmers (Lord) [death] 1067

TITLE INDEX

Abilities, Relative, in Primitive Groups (*Review*), 774
Académie des Inscriptions et Belles Lettres, Abbé Breuil elected a member of the, 244
Acenaphthene, Colchicine and, as Polyploidizing Agents, B R Nebel, 257 , Prof D Kostoff, 753
Acetylcholine in Nervous Tissue of Crustaceans, Occurrence of, and its effect on the Crab Heart, Dr J H Welsh, 151 , Hydrolysis, Clark and Raventós, 1084
Acids, Aspartic and Glutamic, Decarboxylation of, Prof A I. Virtanen, P Rintala and T Laine, 674
Aconite, Crystalline form of, G. Cosàro and J Mélon, 587
Acquired Physiological Characters Inheritance of, Precocity, P Lesage, 968
Actinopterygian Fishes from the Lower Carboniferous of Glencartholm, Eskdale, Dumfriesshire, J A Moy-Thomas and B Dyne, 128
Admiralty Laboratories at Sheffield, 1131
Adreno-Genital Syndrome, Chemical Studies on the, Prof G. F Marrian and G C Butler, 400
Adsorption Potentials and Ageing Liquids, G Ehrensvärd and L G Sillén, 396
Aerial Insect Fauna, up to 300 ft , Composition of the, J. A Freeman, 153
Aero-Engines, New Cooling System for, 284
Aeroplane Wings, Frosting of, Rideau and Ducret, 173 , Height Record, New, by Lt -Col M Pezzi, 790
Africa Fauna and Flora of, Protection of the, 183 , Northern Central, The Geological History of, Dr K S Sandford, 220 , Vegetable Poisons of, Dr G Cufodontis, 406 , Standards of Living in, Dr Margaret Read, 541
African Pygmies, Craniology of, Prof J Mateigka and Prof. J Maly, 722 , Problems, International study of, 744 , Survey An, a Study of Problems arising in Africa south of the Sahara, Lord Hailey (*Review*), 939 , Bureau, An, 1093
Agar Isolation of an Anhydro *l* Galactose Derivative from, S. Hands and Dr S Peat, 797 , Isolation of an Anhydro Sugar Derivative from, Dr E G V Percival, J C Somerville and I A Forbes, 797 , 3 6-Anhydro-*l*-Galactose in, Dr E G V Percival and I A Forbes, 1076
Agricultural Research Council, Earl of Radnor and Sir Joseph Barcroft appointed members of the, 32 , Policy, a Long term, Prof R G Stapledon, 348 , Research Scholarships and Awards, 351 , Research Council Third report of the, 426 , Constitution and Functions of the, 506 , Policy, Long-term, Ley-Farming and a, Prof R G Stapledon, 597 , Research in India, 964
Agriculture Tropical, A Note book of, Prof R C Wood Second edition (*Review*), 776 , Insects and Fungi in, Sir Albert Howard, 801 , The Organisation of, with applications to South Africa, Prof H D Leppan (*Review*), 855 , The Revival of, a Constructive Policy for Britain (*Review*), 895 , Colonial Directors of, Report and Proceedings of the Conference of, July 1938, 1135
Air Survey and Archæology in Germany, O G S Crawford, 15 , -borne Traffic and Infectious Diseases, Regulations against, 69 , Viscosity of, and the Electronic Charge, Prof H R Robinson, 159 ; An Encyclopædia of the, E L Hawke (*Review*), 375 , The, and its Mysteries, Miss C. M Botley (*Review*), 375 , -Flow at Surfaces, Dr H C H Townend, 402 , Raids, Protection from, 424 , -Raid Precautions, Two Publications of the British Steelwork Association, 746 ; -Raid Protection, Mathematics of, Prof J B. S. Haldane, 791 ; in an Air-conditioned Building, Ionization of, Dr. F Běhounek and J Kletschka, 956 ; Conditioning in Deep Mines, 1088
Aircraft Development, Composite, 283
Airships, Protecting, against Fire, 747
Airy's Compass Experiments, [1838], 766
Alaska, Inland Ice Field in, 564
Albania, Malaria in, F. L Richards, 1154
Albino Mice, Castrated, Annual Cycle of Responsivity of, to Œstrone Injection, Dr J Duszyńska, 673
Alchemy The Newer, based on the Henry Sidgwick memorial lecture delivered at Newnham College, Cambridge, November 1936, late Lord Rutherford (*Review*), 592
Alcohol, Studies in, W W Jetten, 1082
Algebra, Advances, C V Durell and A Robson. Vols 2 and 3 (*Review*), 691
Algeria To day, Dr T Greenwood, 1128
Alimentary Exudative Diathesis, Dr H Dam and J Glavind, 1077
Alkali Earth Hydrides, Correlations between Electronic States of Atoms and Molecules in the, Dr B Grundstrom, 614
Allium amplectens, A Triploid Asynaptic, from California, Dr A Levan, 118
Allopregnanolone, Progesterone and, Isolation of, from the Adrenal, D Beall and Prof T Reichstein, 479
Allotropie, Die Theorie der Komplexität und der, Prof A Smits (*Review*), 892
Allotropy, The Theory of (*Review*), 892
Alloys Superconductive, Transition Temperatures of, Dr H Jones, 611 , of Iron and Chromium, The Vol 1 Low-Chromium Alloys, A. B Kinzel and W Crafts (*Review*), 936
Aluminium Active, obtained by Igneous Electrolysis, A Chrétien and J Bisch, 547 , Potassium and Magnesium (*Review*), 553 , -Copper Alloys, Age-hardened, Structure of, A Guinier, 569 , G D Preston, 570 , Amalgamated, Action of Water Vapour on, M Blumenthal, 1049
American Mathematical Society, Jubilee of the, 389 , British and, Associations, Co-operation between the, 409 , Association for the Advancement of Science Virginia Meeting, 845 , Indian Place-Names, Dr J P Harrington, 960
Amino-Acids containing Deuterium, Use of, to follow Protein Production in the Organism, H H Ussing, 399
2 Amino a-Methyl Altroside, "Methyl Epiglucosamine" and, Dr G J Robertson, W H Myers and W E Tetlow, 1076
Ammonia and its three Methylated Derivatives, Dependence upon state of the Dielectric Polarizations of, Dr R J W Le Fèvre and P Russell, 617 , Photochemistry of, Dr H. W Melville and E A B Birse, 1080
Amphibien und Reptilien Griechenlands, Die, Prof F Werner (*Review*), 314
Anatolian Civilizations, Early, Miss Winifred Lamb, 988
Analyse des courbes, surfaces et fonctions usuelles, intégrales simples, Prof P Appell Tome 1 Cinq édition entièrement refondue par Prof. G Varilon (*Review*), 1139
Anatomy Surface and Radiological, for Students and General Practitioners, Prof A B Appleton, Prof W. J. Hamilton and Dr I C. C. Tchaperoff (*Review*), 555 , Comparative, Laboratory Studies in, Dr W C Senning (*Review*), 732
Ancients and Moderns a Study of the Background of the "Battle of the Books", Prof R F. Jones (*Review*), 269
Anderson, Sir James, and Steam Wagons, [1835], 85
Angiosperm Embryo Sacs, P Maheshwari, 172
Angkor : Towards, in the Footsteps of the Indian Invaders, H G Q Wales (*Review*), 736

3 6 Anhydro Methyl Galactosides, Transformation of *a* and *β* Forms of, Prof W N Haworth, J Jackson and Dr F Smith, 1075 *l* Galactose in Agar, Dr E G V Percival and I A Forbes, 1076
Animal Locomotion, 513, Production, Horizons in, Discussion on, J Edwards, 530, Respiration, Oxygen Isotopic Exchange in, Dr J N E Day and P Sheel, 917 Life in Fresh Water a Guide to British Freshwater Invertebrates, Dr Helen Mellanby (*Review*), 935
Animals, Science and the Welfare of, 746
Annelida, Onychophora and Arthropoda, Evolution of, R E Snodgrass 961
Annual Register, The, 1937, Edited by Dr M Epstein (*Review*), 56
Anol, Œstrogenic Activity of A Highly Active Phenol Isolated from the By products, N R Campbell, Prof E C Dodds and W Lawson, 1121
Antarctic Research in the (*Review*), 52, Marine Research in the, G E R Deacon, A W B Powell, 583, A H Laurie, 584, My Last Expedition to the, 1936–1937, L Christensen, 826
Antarctica and Glacial Ages, Prof E W MacBride, 97, J Reid Moir, Prof E W MacBride, 438, Rev W L S Fleming, 537, Prof E W MacBride, 538, Prof F E Zeuner 760, Prof A P Coleman, 998
Anthocyanin Types, Some New, J R Price, Violet C Sturgess, Prof R Robinson and Gertrude M. Robinson 356
Anthocyanins Occur in Bacteria ?, Do, D Erikson, Dr A E Oxford and Prof R Robinson, 211
Anthropological and Ethnological Sciences, International Congress of, M C Burkitt, 363
Anthropologist, The Credo of an (*Review*), 371
dl a Tocopherol, Anti Encephalomalacia Activity of, Dr H Dam, J Glavind, O Bernth and E Hagens, 1157
Antigens and Antibodies, The Chemistry of, Prof J R Marrack (*Review*) 316
Antiquities of South Africa, Preservation of, 1089
Antirrhinum, Downy Mildew of the, D E Green, 172
Apes, Men and Morons, Prof E A Hooton (*Review*), 371
Apoda (Amphibia), The Tetrads in, B R Seshachar, 757
Apple Shoots, Ash Content of V G Vaidya, 621, Storage, Kidd and West, 1165
Apples, Variation in Keeping Quality of, T N Hoblyn, 80
Aquaria, Public, Designing of, J Hornell, 44
Arabia, South West, Archæological Exploration in, 168
Archaic Vertebrates and Evolutionary Principles, Prof J Graham Kerr, 1101
Archæological Expedition to Swat and Afghanistan, Results of the Recent, in Relation to the Present Position of Indian Studies in this Country, E Barger, 1046
Arctic Fauna, Dr B P Uvarov, 405, Fauna of Eurasia and its Origin, Prof N J Kusnezov, 405, Harpooner a Voyage of the schooner *Abbie Bradford*, 1878–1879, R Ferguson (*Review*), 856
Argyll National Forest Park Guide, Edited by Prof J Walton, 18
Aristotle, Parts of Animals with an English translation by Dr A L Peck, Movement of Animals, Progression of Animals, with an English translation by Prof F S Forster (*Review*), 96
Armadillidium vulgare Latr, Genetics of, H W Howard, 1038
Arms Race of 1909–13, The, Dr L F Richardson, 792
Armstrong's Improved Water Wheel [1838], 1132
Aromatic Nitration, By products in, Prof G M Bennett and Dr P V Youle, 356
Arsenic Compounds, Aromatic, A New Synthesis of, Dr W A Waters, 1077
Artemia salina (L) var *principalis* Simon, Relation between Internal and External Media in, H Warren, D Kuenen, and L G M Baas Becking, 1049
'Aryans' in Italy, 167
Ascidian and Sea Water, Internal Fluid of, S Kobayashi, 960
Ascorbic Acid in Plant Tissues, Combined, H Scarborough and Dr C P Stewart, 40, Oxidation of, Inhibiting effect of Sodium Chloride on the, A Høygaard and H W Rasmussen, 293
Ashmolean Society, [1838], 806
Asia, South Eastern, Geological and Archæological aspects of, Dr H de Terra, Father P Teilhard de Chardin and Dr H L Movius, 275; 283
Asiatic Society, [1838], 886, 1170
Aspartic Acid, Enzymic Deamination of Prof A I Virtanen and J Erkama, 954
Asphalt Bitumen Pitch (*Review*), 654
Asphalts and Allied Substances their Occurrence, Modes of Production, Uses in the Arts and Methods of Testing, H Abraham Fourth edition (*Review*), 654
Assam Hills, Cultural Change in the, T C Das, 401
Astronomical Union, International, Sixth Triennial Meeting, 364, Sir Arthur Eddington elected president of the Executive Committee, 365, Thought, Growth of (*Review*), 647
Astronomy, A Hundred Years of, R L Waterfield (*Review*), 647
Astrophysical Methods and Problems (*Review*), 496
Astrophysik, Herausgegeben von Prof B Strömgren (*Review*), 496
Athenæum, The, and School Buildings, 265, and Steam Navigation [1838], 1170
Atlantic Flight with 'Pick a Back' Start, 201
Atmosphere, Daily Exploration of the, by *Radio sondes*, its Development on Land and on Sea, R Bourgeois, 887, in Mines at Great Depths, Engineering Problems Associated with the Improvement of Temperature and Humidity Conditions of the, Dr J H Dobson and Dr W J Walker, 1086
Atmospheric Condensation Nuclei, Diffusion and Fall of, J J Nolan and P J Nolan, with an Appendix by P G Gormley, 180, Phenomenon, A Curious, A S E Ackermann, 482, Pollution at Wellington, New Zealand, C E Palmer, 580, Investigation of Twenty third Report of the, 639
Atmospherics, Reflection of, by the Ionosphere, Prof T H Laby, F G Nicholls, A F B Nickson and J J McNeill, 353
Atomic Realism (*Review*), 92, Elements 43 and 61, H Jensen, 121, Weights and Isotopes, 362, Physics, An Outline of, Members of the Physics Staff of the University of Pittsburgh Second edition (*Review*) 592, Absorption Coefficients and Transition Probabilities, Dr F L Mohler, 1160
Atomkerne Die, Grundlagen und Anwendungen ihrer Theorie, Dr C F von Weizsäcker (*Review*), 592
Attentional Adaptation, Kymograph Studies of Physiological (Respiratory) Concomitants in Two Types of, Dr T Burrow, 156
Audubon, The Naturalist a History of his Life and Time, Prof F H Herrick Second edition (*Review*), 645
Aurora Borealis of May 12, 1938, E Esclangon, 86, Rays, Blue Sunlit, and their Spectrum, Prof C Störmer, 1034
Auroral Spectrum, Atomic Lines in the, Prof L Vegard, 670, Displays of September 14–16, Very Small Intensity of the Red OI Triplet during the, Prof L Vegard, 831
Auroras, Generation of, by Means of Radio Waves, Prof V A. Bailey, 613
Australia Scientific and Industrial Research in, 45 Aborigines of, Protection of the, Dr D F Thomson, 106, Official Year Book of the Commonwealth of, Dr R Wilson (*Review*), 191, Pasture Improvement in, A McTaggart, H C Trumble and C M Donald, 216, Aeronautical Development in, 473

Biological Books in 1937, Prices of, Prof R and Maud De Witt Pearl, 428
Biologischen Arbeitsmethoden, Handbuch der Herausgegeben von Prof E Aberhalden Lief 466 Abt 9 Methoden zur Erforschung der Leistungen des tierischen Organismus, Teil 3, Heft 7 (Schluss) Methoden der Vererbungsforschung Methoden zur Zuchtung von Drosophila, Dr G A Lebedeff, Methoden der Erforschung der Vererbungsvorgänge bei Pflanzen, Dr F G Brieger, Methoden und Ergebnisse bei der Zuchtung von Tetriginæ, Dr R K Nabours (*Review*), 933
Biologists in Search of Material An Interim Report of the Work of the Pioneer Health Centre, Peckham (*Review*), 134
Biology Animal, Prof L L Woodruff Second edition (*Review*), 457, An Introduction to, E J Hatfield (*Review*), 457, and Marxism, Prof M Prenant Translated by C. D. Greaves (*Review*), 851, Mathematical, Sir D'Arcy W. Thompson (*Review*), 931
Bio-Morphosis, No 1, 470
Biophysics : Mathematical, Physicomathematical Foundations of Biology, Dr N Rashevsky (*Review*), 931
Bio Politics An Essay in the Physiology, Pathology and Politics of the Social and Somatic Organism, M Roberts (*Review*), 138
Birch Wood The Swelling of, Dr N A de Bruyne 570
Bird Flocks and the Breeding Cycle A Contribution to the Study of Avian Sociality Dr F F Darling (*Review*) 595 Song Survey British 1151
Birds of Kenya Colony and the Uganda Protectorate The, Late Sir Frederick John Jackson Completed and Edited by W L Sclater 3 Vols (*Review*), 190 The Way of Capt R B T Kelly (*Review*), 659 British The Handbook of, H F Witherby (Editor) Rev F C R Jourdain N F Ticehurst and B W Tucker Vol 2 (Warblers to Owls) (*Review*) 1053 of Britain (*Review*) 1053
Birkbeck College, One hundred and fifteenth anniversary 1069
Birmingham University gift by Lord Nuffield, 64 Hospitals Centre 65 gifts to appointment as lecturers of Miss L Phillip Dr Thelma Mouat and Dr R W Pohl, 86, award of doctorates, 179
Birth rate Decline Diagonal Law of, R S Barclay and Dr W O Kermack, 41
Birth Season of, its Relation to Human Abilities Dr F Huntington (*Review*) 593
Births in Scotland, Seasonal Trends of W P Kennedy, 306 Multiple, Frequency of A V T Day 839
Blasting by Electricity, [1838] 926
Blind Landing System at Aerodromes 947
Blindness, Advisory Committee on appointments to the, 287
Blood Group Genes, Mutation of the Dr R Elsdon Dew, 575, Ammonia and the Deaminases of Adenosine and Adenylic Acid, Prof F J Conway and R Cooke, 720 Corpuscles, Diffusion of Phosphate Ions into, A H W Aten jun, Prof G Hevesy 871
Boden Pilze Die mikroskopischen ihr leben, ihre verbreitung sowie ihre oeconomische und pathogene Bedeutung, Dr A Niethammer (*Review*), 896
Bode s Law and the Systems of the Planets and Satellites, J Miller 670
Bombay University Dr K Venkataraman appointed Mody professor and head of the department of chemical technology, 765
Bombyliidæ of Palestine, late Major F E Austen (*Review*) 596
Bone Tumours and Œstrone F C Pybus and Miss E W Miller, 872
Boron, Disintegration of, with Emission of Deuterons I Zlotowski, 491
Botanic Gardens in Regent s Park, New [1838], 682
Botanical Society of Edinburgh [1838] 846, Society, [1838], 968
Botany British, History of, A Chapter in the (*Review*), 51, in Britain (1875–1935) Sixty Years of, Impressions of an Eye Witness, Prof F. O Bower (*Review*), 51, Cryptogamic, Gilbert M Smith 2 Vols (*Review*), 234 General, A Textbook of, for Colleges and Universities, R M Holman and Prof W W Robbins Fourth edition (*Review*), 498, East Asiatic A Bibliography of, E D Merrill and E H Walker (*Review*), 596
Boundary Waves at a Surface of Discontinuity, Prof K Sezawa and K Kenai 962
Bovine Tuberculosis, Eradication of, 69
Bradford Technical College, R Williamson appointed Harlow fellow, 287
Brazil Botanical Research in, 921
Bread Our Daily, A Geography of Production, Sir Daniel Hall (*Review*), 555
Brewing Institute of, Research Fund Committee of the, Sir Gilbert Morgan appointed chairman of the, 469, Science and Practice, H Lloyd Hind Vol 1 Brewing Materials (*Review*), 651
Brickmaking by Machinery [1838], 1048
'Bridlington Crag' Shells, T Sheppard, 359
British Museum (Natural History), Acquisitions at the, 18, School of Archæology at Rome, H N Savoury elected to the Rome scholarship, 70, Museum

(Bloomsbury) retirement of R L Hobson, 105 Empire Cancer Campaign, grants from the, 108, Association Cambridge Meeting Sectional Programmes, 122, Museum (Bloomsbury), retirement of T A Joyce, 146, Scientific and Technical Books Select List of Standard Second edition, 170, Graham Land Geology of, Rev W L S Fleming, 172 Association Cambridge Meeting of the, General Arrangements 195, Museum (Natural History), Acquisitions, 204 Empire Cancer Campaign Lt Col W L Harnett appointed medical secretary to the Clinical Cancer Research Committee of the 206 Speleological Association, Third Annual Conference, Dr R R Marett elected president 284 Association at Newcastle on Tyne in 1838 305 Isles, Humidity in the, 865, Association at Newcastle on Tyne, [1838], 366, Sir Albert Seward elected president for 1939, 386, The Cambridge Meeting of the, 387, and American Associations, Co operation between the, 409 Museum Research Laboratory of the Dr H J Plenderleith appointed deputy keeper of the, 642 Laboratory, retirement of Dr A Scott from the honorary directorship of the, 697 (Bloomsbury) Accessions to the 698 Rainfall, 1937 (*Review*) 735, Museum (Natural History) Acquisitions at the, 786, Hardwoods Utilization of, W A Robertson 825, Electrical and Allied Manufacturers Association Objects of the 869 Museum (Natural History), impending retirement of Dr W D Lang W N Edwards appointed keeper of the department of geology, 870, (Bloomsbury), Recent Acquisitions 947, *Journal of Dermatology and Syphilis*, Oct 749, Museum (Natural History) Acquisitions, 989 School of Archæology at Athens, Annual Meeting 1032, Wild Animals, The Observer s Book of, W J Stokoe (*Review*) 1058, Association Dundee Meeting, appointment of sectional presidents, 1073, Museum (Natural History) Life size Model of a Blue Whale 1110, (Bloomsbury) Mesolithic Pit dwellings at Farnham, Surrey, Accessions to Collections of British Antiquities, 1110, Coal Utilisation Research Association, 1111 Isles Humidity in the, R G Bateson, 1123, Institute of Radiology Annual Congress X Rays—their Influence in Pure and Applied Science Dr G Shearer (Mackenzie Davidson memorial lecture) 1131, Museum (Natural History) Dr E I White appointed deputy keeper of geology and F A Bannister deputy keeper of mineralogy in the 1155

No 3583 SATURDAY, JULY 2 1938 Vol 142

Education and Intellectual Freedom

IN a noteworthy address at the annual dinner of the University of London held on May 13, the American Ambassador, Mr Kennedy, stressed the importance of the remaining free universities of the world as champions of the undisturbed liberty to seek and expound truth as it is and not 'truth' as it ought to be—in the interests of some totalitarian scheme. The spirit of tolerance and free inquiry has only been kept alive in Great Britain and in the United States by strenuous endeavour, and in spite of our enviable position we should not think that in either country the fight is over.

Mr Kennedy's reminder of our responsibility to truth and justice was coupled with a warning of the danger which threatens to-day not only the quest for new truths regardless of their immediate value, which is the basis of true learning and scholastic integrity, but also education itself, in a world which has seen famous scholars driven into exile and universities staffed only by those who openly subscribe to a dominant political creed. Schools, colleges and universities are being forced to teach not what the professors know to be true, but rather what the political heads of the State want their youth to believe is true. Never was greater vigilance called for even in the free countries to see that the schools do not become the organs of any political party temporarily in control of the destinies of the State, or to permit them to mirror any teaching except the truth as nearly as it is possible to ascertain and impart truth.

It is well, indeed, to be reminded that the struggles by which academic freedom was established in the past are by no means over, for to recognize the threat of a harsher bondage of learning to politics is a long step towards rallying forces to meet the danger. Moreover, the conditions to-day tend to hinder the free exchange of ideas between scholars of different countries, through which the universities can function as agents of international appeasement. On one hand, eminent men of learning are liable to be excluded from certain totalitarian countries, while on the other, the utilization of academic and scientific activity for the advancement of national political ends characterizing those countries has in turn led to a more cautious attitude in other countries in expanding facilities for the movement of professors, lecturers or students from such countries, except under the most express guarantees.

Upon this situation, the recent volume* by Mr S. H Bailey, issued by the Royal Institute of International Affairs, throws a flood of light. While Mr Bailey sets out with admirable lucidity the historical growth, the nature and the extent of the provision now made for research in universities and non-academic institutions and for teaching in higher, secondary and adult education on international relations in a number of European countries and in the United States of America, he never allows his survey to be overburdened with detail. Detail is there indeed, sufficient for those who wish to follow up particular aspects of the survey more fully, but even more valuable is Mr Bailey's analysis of the factors involved and the conditions of progress in this field. Here he brings to light the special responsibilities of the universities, both in the field of research and in the moulding of an informed and alert public opinion, without which even the most enlightened leadership is doomed to frustration and failure

---

* International Studies in Modern Education By S H Bailey. Pp. xvii + 309 (London Oxford University Press, 1938) 15s. net.

Discussing the position of research in international relations, Mr Bailey points out that the principal obstacle to objective investigations is not the inadequacy of the financial resources, the dearth of trained personnel or the absence of adequate materials, but the encroachments upon intellectual freedom. The full admission of the principle of intellectual freedom is a vital condition for the objective study of international relations, no less than for scientific work of any kind The twist which has been given to the minds of many in the authoritarian State who carry the responsibility for guarding the scientific tradition makes it difficult to rely upon the objective value of the work of institutions in those countries Even in scientific work, it is almost impossible to estimate at any given moment the pressure of the unseen hand of an authoritarian Government, and the collective study of international relations can easily become a travesty A resonant dogmatism drowns the quieter tones of the cautious comment and query of the scientific investigator, and an exchange of ideas, accompanied by their critical examination, becomes impossible

Mr. Bailey's sober criticism here and elsewhere should go far to convince scientific workers of the reality of the threat in every field, and of the importance of a determined effort for the rigid maintenance of a high academic standard no less in international studies than in scientific questions in the narrowest sense of the word, even at the cost of an apparent slowing down of the pace of development The situation is essentially similar with regard to neutral institutions unconnected with a university, such as the Institute of Pacific Relations and the Royal Institute of International Affairs. It is as necessary as with the universities that such institutes should be independent of political or other affiliations, and be precluded from expressing a corporate opinion if the research conducted by them is to be of real value

Besides outlining the essential conditions for research institutions in this field, Mr. Bailey's notes on the development of the study of international relations in higher education deserve attention. He comments on the devastating effect in the social services of intensive specialization and the need for a general view for the comprehension of social phenomena—and the increasing difficulty of obtaining it—the tendency of students in one branch to overlook the contributions which workers in other fields can make to their work, and on the obstacle which is presented by preoccupation with professional training. In respect of adult education, his criticism of both the issue and the supply of publications of all kinds deserves attention, particularly in respect of those coming from organizations advocating policies, whether Government or not

In both the sphere of research and in the university, the emphasis on the need for objective investigation and objective teaching is unmistakable, and Mr Bailey directs attention particularly to the influence of the reaction against objective teaching in secondary education. In Germany, Italy and the U S S R, the educational policy tends not to prevent the study of international relations but to subordinate it to the immediate political needs of the regimes in power. This in turn leads to a reaction in the field of secondary education corresponding with the close watch over their academic reputations kept by universities in countries where freedom of expression of opinion is still permitted Educationists in such countries hesitate to encourage the movement of teachers and children to countries where freedom of expression of opinion is no longer tolerated and an active policy of political indoctrination pursued, and are also reluctant to receive teachers from authoritarian countries without the most explicit guarantees and the provision of safeguards against foreign propaganda

The situation is thus not one which scientific workers can contemplate without concern. The obstacles to free exchange of thought across national frontiers no less than inside many of those frontiers are growing just when science has in many ways annihilated distance and incredibly multiplied means of communication. Even the almost unlimited possibilities offered by the natural and applied sciences for conveying to the mind a sense of the unity of knowledge and the ubiquitous results of scientific research, and in encouraging the development of the sense of human solidarity and reciprocal good will, can scarcely be utilized in such an atmosphere All the more important it is

that scientific workers should not shirk their responsibility for upholding freedom of thought and investigation in countries where this principle is still honoured, of guarding against abuse of that freedom, of extending the spirit of impartial scientific inquiry into the many complex social, economic and international problems at present so largely dominated by prejudice, and of promoting within their own land and across its frontiers a spirit of respect for facts and the rights of others Upon such a basis alone can be based alike the citizenship which permits enlightened leadership and the understanding and good will which establish justice and peace between nations.

A Philosophy for Socialism

A Philosophy for a Modern Man
By H. Levy Pp 287. (London Victor Gollancz, Ltd , 1938) 7*s* 6*d*. net

ALARMED discontent pervades the minds of most who reflect on the present state of our social organization, or who have to play some conscious part, small or great, in its conduct Some diagnose the trouble as due to an upheaval in the ordained stratification of society, accompanied by and made more evil by failure in the mutual duties of the respective strata (or classes). Their remedy, in general terms, is to restore order mitigated by a cautious benevolence But in their camp are not a few fleeing travellers throwing their load to the pursuing pack in a flurried haste, which, however, does not prevent a determination to make their own property the last sacrifice

Others see that change is inevitable and press ruthlessly towards the realization of their own conception They abstract social organization from the individuals which compose a society and would give to these a meaning and indeed an existence only for and through the society They, like the first group, believe in duty, and that true freedom and happiness can be found only in obedience to duty, but it is fair to make the distinction that the new categorical imperative depends on the will of certain individuals, the old on the fact or the tradition that it is the will of God

Those who wish to understand the object of Prof Levy's sincere and vivid book may well begin by reading first the last chapter He thinks that efforts to "harness the forces of production to the well-being of the people" must fail, and that the failure is inevitable, because hitherto "every form of society has been organised internally to serve the material and spiritual interests of a dominant class, by using the labour power of a subordinate class" His hope is for the emergence of a non-capitalistic, one-class organization of society.

Now the first of the groups to which I have referred believe that their political creed is based on a religious and metaphysical philosophy; the second group plead in their support a somewhat crude adaptation of the Hegelian dialectic Prof. Levy hopes that he has supplied a philosophy which will show that the change he wishes is in the natural order of the universe, is, in fact almost inevitable, but can be accelerated by the conscious activities of men of good intention It follows closely Marxian dialectical materialism, but is reinforced by interpretation of the history of recent years, and by Prof Levy's wider knowledge of economics and of physical and natural science "For us," he writes, "the problems of philosophy are resolved into those of guiding ourselves and others towards this classless society "

I am not quite sure that philosophy with an alien purpose is likely to be a very sound philosophy, or that the wish to make it a support for a social doctrine may not lead it into waters as strange as it was led by the intention to prove or to disprove dogmatic religion But probably I am abnormal in that respect, as it seems to be a comforting habit to attach a philosophy to every new social or scientific discovery, and without doubt Prof Levy has compounded a very fortifying draft

Within a brief space, it is impossible to describe, and therefore foolish to pretend to criticize this "Philosophy for a Modern Man" It begins by explaining a methodology which employs what is to me the new and illuminating conception of 'isolates' An isolate is a thing or process, or group of things and processes, the behaviour of which you study either by isolating it physically as in a laboratory experiment, or by abstraction in thought, so as to understand how far that behaviour is self-determined But outside the conditions of the laboratory, and to a smaller extent even within them, your isolate is in contact with a larger isolate, and that again with one still larger. With your new knowledge you can now study the interactions between internal and external relations. But you have always to remember that your object of study, whether statistical or qualitative, is an isolate, and a way to knowledge, rather than knowledge itself.

The world is a changing world and every isolate and its relations are in constant change. Quantitative changes pass into qualitative changes Under the very stringent conditions of laboratory experiment, such changes are sometimes reversible, but in biological events the series of changes, although they follow in orderly series, are not reversible Hence the observation of experiments has to be replaced by the interpretation of history. It follows, therefore, that a philosophy of history has to be part of the philosophy of a modern man, and one of the most cogent and illuminating parts of Prof Levy's book is his description and interpretation of the rise and failure of previous organizations of society, leading to his thesis that we are at present in a critical phase which will pass inevitably into the one-class society of the future

P CHALMERS MITCHELL.

Skull Morphology

The Development of the Vertebrate Skull
By Dr G R de Beer Pp xxiv + 552 + 143 plates (Oxford Clarendon Press, London Oxford University Press, 1937) 30s net

IT is more than sixty years (1877) since the appearance of the first general text-book on "The Morphology of the Skull" by Parker and Bettany, a work excellent in its day but now out of date The most important general work on the subject since then is the part on the development of the skeleton of the head contributed by E Gaupp to Hertwig's well-known "Handbuch" (1906) It marked a great advance in our knowledge, more especially of the development of the cartilaginous framework of the skull and visceral arches But a vast amount of work has been done since on the skull, and no one has made more important contributions than Dr de Beer himself, whose series of detailed studies on the development of the head and skull in various vertebrates from cyclostome to mammal, published from 1922 onwards, form the basis for this fine monograph illustrated by 143 plates containing a vast number of figures most of which are the author's own

The volume begins with a historical review of work done on cartilage, 'cartilage-bones', and 'membrane-bones', and their relationships from the histological, morphological and phylogenetic points of view There follow discussions on the segmental composition of the skull, the determination of the exact position of its hind limit, and the craniogenic materials of which it is composed. The second, or systematic section, contains detailed accounts of the development of the skull in typical examples of the various groups of Craniata from the lamprey to man A third, comparative, section deals with the general morphological consideration of certain cartilages and bones of particular interest; while in a fourth and general section the author returns to such more general questions as the growth of the skull, the effects of heterochrony, the experimental evidence as to the causal relationships and interdependence of the parts This section also contains most useful summaries of the special characteristics of the various classes

A distinctive feature of this monograph is the detailed account of the relation borne by the skeletal parts to the neighbouring nerves and blood-vessels, and their clear delineation in the figures. The importance of these relations had already been emphasized by Gaupp and particularly by Allis, and they have been worked out in various forms by de Beer with remarkable success

Three main questions are dealt with in this book the fundamental segmentation of the head, and the attempt to trace in development how many segments, corresponding to those of the rest of the body, contribute to the building up of this special region, the development and homology of the various skeletal parts, both cartilaginous and bony, and how far they can be distinguished as constant elements throughout the Craniata, and lastly, the actual phylogeny of the skull and visceral arches in their manifold adaptations in the different groups both living and extinct All fascinating problems

Only a few points can be mentioned in this review It was Balfour who first showed that the head-region consists of segments homodynamous with those of the trunk, and van Wijhe who clearly distinguished between the more dorsal myotomes giving rise to myomeres innervated by the ventral segmental motor nerve-roots, and the more ventral unsegmented lateral plate giving rise to muscles supplied from the segmental dorsal nerve-roots De Beer concludes that there are three, and three only, so-called prootic segments in front of the auditory capsule, and a varying number of metotic segments behind the capsule in different species and groups (for example, nine head-segments altogether in *Squalus*, eleven in *Lepidosteus*, six in *Amblystoma*, nine in *Lacerta*);

that, as shown by Koltzoff, the complete uninterrupted series appears in the embryo and persists even in the adult cyclostome (*Petromyzon*). Moreover, he confirms Ziegler and Goodrich, as against van Wijhe, in maintaining that no segment is suppressed in the region of the third prootic, and that the orderly sequence of myotomes and nerves is here preserved. Further, he shows that in Gnathostomes not more than two myomeres are suppressed behind by the overgrowth of the auditory capsule during the course of development, the sixth of the series being usually the first to produce permanent muscle. Consequently, Furbringer's assumption that a large number of metotic segments have in the course of phylogeny been eliminated, already severely criticized by Goodrich, is here rejected.

The exact position of the occipital joint, which varies in different forms according as more or fewer trunk segments are assimilated from behind and contribute to the formation of the skull, is another point admirably treated. The homology of the trabeculæ cranii has been a subject of much controversy. Long ago, Huxley suggested that they were derived not from the axial chrondrocranium itself but from an anterior pair of visceral arches. From fresh evidence de Beer inclines to the view of Allis that they are, indeed, premandibular arches, and that the pair of gill-slits between them and the mandibular arches has been lost. The text ends with a useful list of problems which remain to be solved by future research.

Throughout full justice is done to the work of previous authors, whose observations and conclusions are carefully considered, and the very complete bibliography at the end of the volume is ingeniously set out so as to refer to the subject dealt with and the page on which the reference occurs.

The writing of such a book must have entailed an immense amount of careful work, and students of the morphology of vertebrates owe a debt of gratitude to the author for having carried it out so successfully. The publishers are to be congratulated on having brought out such a handsome volume at so moderate a price.

Conceptions and Exponents of Human Culture

The History of Ethnological Theory

By Prof. Robert H. Lowie. Pp. xiii+296. (London: G. Harrap and Co., Ltd., 1937.) 10*s*. 6*d*. net.

IN his history of ethnological theory, Prof. Lowie gives a survey of the course of progress in the theoretical study of culture and of the growth of knowledge through the improvement of technique for gathering the requisite information. For these his wide knowledge of the literature of the subject and his critical detachment render him peculiarly well fitted, and he has done so in a most interesting manner. Although the history covers a period of some hundred years, it records the infancy and adolescence of a new branch of learning which only now is attaining recognized scientific status.

The approach by students to ethnology has been very varied. The mental training required for proficiency in law, history, biology, medicine, or philosophy has necessarily given a bias in the several students towards some particular aspect of ethnology and to the manner in which it has been studied. There must also be taken into account the prevalent scientific and philosophical tendencies which must inevitably influence the investigator. For example, ethnologists were irresistibly inclined to adopt the prevailing biological concepts at the time when evolution was in the air.

The subject-matter of ethnology, unlike that of the physical or natural sciences, cannot be discussed purely objectively, as it deals with investigations into human culture and behaviour undertaken by human beings with different personal equations. The conclusions and at times even the integrity of the writers have been criticized by other students, who also exhibit very human traits—lack of poise, rancour, and even distortion being not unknown. The history of ethnological theory is thus bound up with the personality of those who were creating the science, and consequently Prof. Lowie has found it necessary to consider their idiosyncrasies as well as their contributions to ethnology. These personal sketches of dead and living ethnologists are most illuminating and are presented with a dispassionate judgment to which little exception can be made.

The following observations are extracted from Prof. Lowie's final chapter, "Retrospect and Prospect". He refers to four errors that are now definitely discarded: that of culture being a simple function of physical conditions and natural resources. Prelogical primitiveness. Primitive intellectualism. Racialism: since the comparatively small differences in the innate mental endowment of races are not able to account for all the differences in cultural development; such, for example, as the profusion of secret societies in some areas and their absence in others.

There is general agreement that Bastian s genetic law cannot explain specific coincidences While no one has ever denied diffusion *in toto* its importance has been established beyond cavil and what nowadays divides scholars is merely the intensity of their concern with this principle and the nature of their methodological safeguards against error Even the most fervid functionalists occasionally turn to historical sequence As Dr Elsie Clews Parsons remarks Wisdom in ethnology as in life lies in having more than one method of approach Within the space of half a century a number of questions have been settled—so far as we can judge definitively No one now defends the three stage theory of economic progress That promiscuity now exists nowhere and is an unproved hypothesis for the past is the view of most living ethnologists That the family and not the clan is the basic social unit is also widely held though Durkheim still maintains the idea of the priority of the clan

Neither psychology or ethnology can be reduced to the other Ethnology enlarges the psychologist s ken demonstrating the scope of social patterning in individual behaviour The ethnologist inevitably bound to use terms relating to the mind uses the determinations of scientific psychology prophylactically against the snares of vulgar psychology and constructively in refining his analysis of regional differences and of particular processes

Being a science ethnology implies an orderly arrangement of its data the verifiability of its findings a logical basis for its conclusions But in conforming to the canons of all science it must not adopt the particular techniques of physics biology or geology except where the cultural data as such demand such recourse

A C HADDON

Mathematics for Economists

Mathematical Analysis for Economists
By R G D Allen (London School of Economics and Political Science Studies in Statistics and Scientific Method edited by A L Bowley and A Wolf) Pp xvi + 548 (London Macmillan and Co Ltd 1938) 31*s* 6*d* net

THE aim of this book is to provide a course of pure mathematics that will be useful to students of economics The earlier chapters which deal with numbers and variables and their representation with analytical geometry the elements of the calculus etc will as intended by the author be helpful and valuable to the student of economics who has little mathematical equipment but must learn more in order to follow the modern treatment of economic theory for which economists are considerably indebted to the late Prof Alfred Marshall and later writers The later chapters deal with functions of two or more variables with differentials problems of maximum and minimum values differential equations expansions and determinants while a final chapter discusses some problems in the calculus of variations At certain stages especially in the later chapters problems definitely connected with economics are discussed from the theoretical point of view but the author has relied largely on a careful choice of examples to lead the reader from the mathematics to the practical application These examples are particularly well arranged and have been chosen with considerable skill so that taking the book as a whole we think that it will be found interesting to many economists who have passed the stage of student in the educational sense but are still students in the wider sense of the term

There is little in the way of adverse comment that need be urged against the book but we may suggest that in future editions an occasional verbal rearrangement might be advantageous for example on p 297 where in dealing with partial derivatives the author refers to two vertical sections perpendicular to each axis the wording may give the impression that there are only two possible vertical sections It becomes clear on the next page that this is not what is meant but a slight alteration would ease the path of the reader

From time to time mathematical books are published which have been prepared by the authors for particular groups of students and in the not wholly convincing short bibliography one book is mentioned Calculus made Easy which was originally intended for engineering students this is a long way from economics A type of work bearing some points of contact with economics is that of the actuary but the mathematical text book used by actuarial students in Great Britain has little likeness to the book before us Mr Allen might however in dealing with interest adopt for future editions the international actuarial notation

In reading this interesting book it was borne in on us that though each type of student will inevitably read his mathematics for a specific reason it would sometimes be wise for him to put aside books which deal with mathematics from his own point of view and to study instead books written for a different type of student Such a course would not only improve his mathematical equipment but also it would convey to him that there is a field of work outside his own which may be linked with his by the fundamental mathematics or in other ways The thoughtful student might thus be led to a broadminded sympathy with other subjects and to the possible enlargement of his own Mr Allen s book contains much that could be read by students who have no direct interest in economics and it can be whole heartedly recommended W P E

Metallic Systems

Die heterogenen Gleichgewichte
(Handbuch der Metallphysik herausgegeben von Prof Dr G Masing Band 2) Von Prof Rudolf Vogel Pp xxiii +737 (Leipzig Akademische Verlags gesellschaft m b H 1938) 68 gold marks

THE previously published parts of the Handbuch der Metallphysik have dealt with metallic structure and the plastic working of metals The high standard set by those parts of Prof Masing s fine work is worthily upheld by this volume the subject of which is more difficult to treat successfully because of its immense scope The author has not attempted to confine attention to metallic systems but for reasons which are explained in an introduction and with which few will disagree has taken the broadest point of view concentrating on physico chemical fundamentals and illustrating them by examples of both non metallic and metallic systems

The book is divided into five sections in the first of which the principles of thermodynamics are somewhat briefly stated in order to explain the phase rule and the influence of temperature and pressure on equilibrium The second section on single component systems deals with vapour pressure and melting point curves the triple point the derivation of the *p t* diagram from free energy considerations and polymorphism and describes the cases of sulphur ammonium nitrate silica water phosphorus and *allotropic metals* The thermodynamic criteria of equilibrium—the *minimum free energy of the system and the equal* partial free energies of the components—are also explained and their implications illustrated by free energy diagrams Binary systems are considered in the third section which is about equally divided between equilibria in the presence of a vapour phase and condensed systems in which the pressure variable can be neglected Particular metallic systems are not discussed in detail but a list is given of references to the literature concerning more than 450 systems The thermodynamic treatment of equilibrium of the second section is here extended to systems of two components

In the fourth section equilibria of three component systems in the presence of a gaseous phase occupy only 30 out of 350 pages the remainder being of immediate interest to the metallographer since it provides a meticulously thorough explanation of the possible types of ternary equilibrium diagram illustrated by detailed descriptions of the aluminium magnesium copper iron nickel phosphorus iron nickel tungsten iron carbon cobalt and iron iron sulphide iron carbide systems A list is given of references to the literature dealing with more than 200 ternary metallic systems The use of free energy diagrams is further extended The comparatively small amount of knowledge available concerning systems of more than three components is evident from the shortness of the final section in which the difficulties of presentation and the vast field awaiting exploration are clearly indicated A list of 22 quaternary metallic systems which have been investigated emphasizes the artificiality of the distinction between Legierungen ohne Eisen and Legierungen mit Eisen by including among the latter the work of Gwyer Phillips and Mann on the Fe Al Cu Si system

This book is not to be recommended for reading in the train and most metallurgists will probably require a large dose of Lewis and Randall before digesting the whole of it On the other hand it *is not sufficiently comprehensive to form a reference* book on heterogeneous equilibria for the physical *chemist It is in fact a compromise which attains* considerably more than might be expected from *part of a treatise on* Metallphysik for it not only explains the characteristics of equilibrium diagrams *for metallic systems* but it also presents to the metallurgist a wider scope than he is wont to consider and encourages—indeed almost demands—wider reading Comprehensive references are given and the indexing is adequate The publishers have done their work well good printing excellent diagrams and a handsome binding complete a valuable addition to metallurgical literature

Constructive Democracy

By Sir Ernest Simon, the Rt Hon. the Viscount Halifax, Arthur Bryant, R. Bassett, the Marquess of Lothian, the Rt Hon C. R Attlee, Sir William Beveridge, E J. Patterson, Sir Alfred Zimmern, H. D. Henderson, Sir Arthur Salter, Moritz J. Bonn Pp 249. (London : George Allen and Unwin, Ltd , 1938) 7*s*. 6*d*. net

THERE can now be few scientific workers who are unaware of the threat to science itself which the disappearance of the spirit of free inquiry in the totalitarian States constitutes, and to any such Sir Alfred Zimmern's pertinent address on "Learning and Leadership" can be heartily commended. The problem of establishing in the democratic States conditions under which the fullest use can be made of science grows ever more urgent in the interests of science no less than of democracy itself. Without the spirit of free inquiry the fundamental disciplines themselves decay, and without them applied science cannot flourish long. This timely essay is both a warning and a challenge to thought and co-operation from scientific workers themselves, and for it alone the volume would be welcome.

There is, however, much else in these essays or addresses, for all their diversity, which has claims on the attention of scientific workers. Sir William Beveridge, for example, writing on "Planning under Democracy", reiterates his proposal for an economic general staff as a means of assisting the impartial scientific study of political, social and economic questions. Between them, these essays state very fairly the claims which democracy has upon the serious attention of the scientific worker, directions in which he might well seek to qualify himself as a citizen without impairing his professional standards or code, and ways in which he might co-operate in the solution of problems urgently demanding attention if standards and ideals which he cherishes no less than other citizens of a democratic State are not to be overthrown by the dictatorships.

The Cause of Cancer

By David Brownlie. Pp. viii + 208. (London : Chapman and Hall, Ltd., 1938.) 7*s*. 6*d*. net

THE author, a fuel technologist, presents the theory that most human cancer is caused by the entry into the body, mainly in the food, of carcinogenic compounds formed by carbonization. He would have us believe that the cooking of food in internally heated gas ovens, and the smoking of meat and fish, are the principal sources of these dangerous substances, but that the breathing of traces of leaking and partially unconsumed domestic gas also contributes.

The evidence here presented is quite inadequate to support the author's theory with any sound basis of experience. In fact, we may even ask if the high-boiling carcinogenic hydrocarbons are actually present in the gas supply. There are also a number of facts which seem to deny that any but a restricted range of cancers could be due to such a cause. For example, two strains of mice may be bred for many generations side by side in the same animal house, receiving the same food, breathing the same (polluted or unpolluted) air ; yet 90 per cent of the females of one strain get cancer while only a small proportion of the other strain suffer from the disease. Moreover, contrary to the author's opinion (p. 20), there is excellent evidence that typical cancer occurs in a variety of animal species. F. D.

Heredity and Politics

By Prof J. B. S. Haldane. Pp 185 (London : George Allen and Unwin, Ltd., 1938.) 7*s* 6*d*. net

THIS book has been skilfully fashioned out of the Muirhead Lectures given by the author at the University of Birmingham last year. It is addressed to such as are unacquainted with the science of genetics, but who are attracted or disturbed by eugenic doctrines. In relation to its purpose, it is an admirable book. Its language is simple and non-technical, yet precise, and its style is smooth and pleasing.

It consists of two parts, the first being a lucid and attractive exposition of the principles of genetics so far as they apply to the human subject, whilst the second half of the book treats with studied fairness of such controversial questions as the fundamental inequality of man, the sterilization of the unfit, the differential birth-rate, the innate superiority of certain races and certain social classes, and the effects of racial crossing. The author is uniquely equipped to deal with these matters, and to those who wish to become acquainted with such scientific knowledge concerning them as exists, and who would care to know what one of the really outstanding intellects of our time thinks about them, this book is strongly recommended. It could be read with great profit by the medical student who seeks an introduction to human genetics. F. A. E. C.

Analytical Chemistry

Based on the German Text of Prof. F. P Treadwell. Translated and revised by Prof William T. Hall. Vol. 1 : Qualitative Analysis. Ninth English edition. Pp. x + 630. (New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Ltd., 1937.) 22*s*. 6*d*. net.

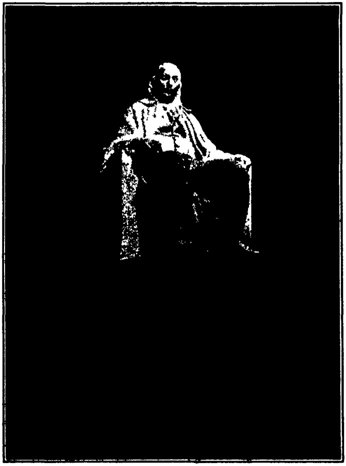
TREADWELL'S "Analytical Chemistry" belongs to the classics of our teaching literature. It now enters its ninth English edition under the guidance of Prof. W. T. Hall. In the interim since the previous edition there have been many changes introduced into modern chemical theory, and these have necessitated alterations in the book. Part 1, dealing with general principles, has been largely rewritten ; part 2 is rearranged in the order of the analytical procedure followed by the student.

Much new material is to be found ; for example, tests based on drop reactions and a certain amount of semi-microchemical analysis. Other matter has been discarded or shortened to keep the book within bounds : for example, the sections on spectroscopy and on the analysis of the rare metals.

It is valuable to have such books kept frequently revised, and the users will owe a debt of gratitude to the author for his labours. Criticism of such a successful work is superfluous.

The Benjamin Franklin Memorial, Philadelphia

THREE days of stately ceremonies, including the unveiling of a heroic white marble statue of Benjamin Franklin, lectures on pure and applied science, a two million dollar philatelic exhibition, military and naval displays, exhibits contrasting the science of Franklin's time with that of to-day, marked the formal dedication of the Benjamin Franklin Memorial on May 19–21, at the Franklin Institute, Philadelphia, Pa



STATUE OF BENJAMIN FRANKLIN IN THE FRANKLIN HALL, FRANKLIN INSTITUTE, PHILADELPHIA

The French Ambassador to the United States, Count René Doynel de Saint Quentin, Herbert C Hoover, former President of the United States, Daniel C Roper, Secretary of Commerce; George Wharton Pepper, formerly a senator of the United States; Roland S Morris, president of the American Philosophical Society and formerly ambassador from the United States to Japan, Sir James Colquhoun Irvine, principal and vice-chancellor of the University of St. Andrews, Scotland, and Dr Louis Martin, director of the Pasteur Institute, Paris, were among the notable figures participating in ceremonies honouring the Philadelphia printer who became a world-famed man of science and statesman.

The annual award of medals by the Franklin Institute; the conferring of degrees by the University of Pennsylvania, which is the outgrowth of an academy founded by Franklin; the participation by thousands of school children in massed choruses and bands and in a colourful "Young Philadelphia Parade"; and a pilgrimage to the new Franklin shrine by representatives of to-day's printing industry were prominent features of the dedication.

"From this time forward the Benjamin Franklin Memorial will be his [Benjamin Franklin's] permanent home, and I extend a hearty invitation to all people everywhere to visit him and make him their friend," said Mr. Pepper in a dedicatory address

The new 'home' of the eighteenth century sage who revealed the identity of lightning and electricity and made important investigations and discoveries in many other fields of natural philosophy, is fittingly located in a classic structure dedicated to scientific progress In the spacious building on Benjamin Franklin Parkway in Philadelphia, the Franklin Institute, founded in 1824 and active in the promotion of science and the mechanic arts, maintains its "Wonderland of Science" Museum, where more than 4,000 action exhibits reveal the part played by science in every-day life; and its Fels Planetarium, noted for its reproductions of the heavens. The spiritual centre of this building, and a public shrine to the memory of the great statesman and natural philosopher, is the new Franklin Memorial. There, in a lofty memorial room inspired by the Pantheon in Rome, rises the heroic statue; a seated figure in white Seravezza marble, more than twice life-size. Upon its huge pedestal of rose aurora marble from Portugal, it extends to a height of 18 feet above the floor The sculptor, James Earle Fraser, whose notable statues, groups and relief portraits grace many parks and public buildings throughout the United States and Canada began work on the Franklin statue five years ago, and has described his own conception in the following words

"A massive figure, tranquil in body with latent power in his hands but with an inquisitive expression in the movement of his head and the alertness of his eyes ready to turn the full force of his keen mind on any problem that concerned life '

In a manner that would have aroused the keen interest of her famous ancestor, ten year old Miss Louisa Johnston Castle of Wilmington, Delaware, a lineal descendant of Franklin, unveiled the statue by turning a searchlight upon a photo electric cell

In the three day programme Franklin was commemorated as "Patriot and Man ', as ' Philosopher and Educator", and as "Printer and Business Man" Special exhibits depicting the advance of science from Franklin's day to the present time, on display in the Wonderland of Science Museum vied with lectures by noted men of science and educators of two continents in the tribute to the great American's scientific achievements Developments in electricity were shown from an electrical machine which Franklin once owned to a modern half million volt surge generator producing man made lightning Progress in printing, 'Poor Richard's' own craft, was demonstrated from a hand press used in Franklin's original printing shop to modern presses that print in four colours Paper making was performed by hand just as it was in Franklin's day, and the entire modern process from pulp to finished paper also was demonstrated on a miniature scale model Fourdrinier paper making machine A replica of the "Pennsylvanian Fireplace", one of Franklin's outstanding inventions was shown in contrast with an exhibition of the development within the last twenty years in automatic oil heating equipment for home use

In a notable series of lectures on pure science, given at the Franklin Institute on May 20, Sir James C Irvine spoke on "Benjamin Franklin in Saint Andrews, 1759 , Dr C E K Mees, director of the Research Laboratory of the Eastman Kodak Company, Rochester N Y , who is a native of Wellingborough, England, and was educated at Harrogate and St Dunstan's, on Photography and the Advance of Pure Science" , Dr Gilbert N Lewis dean of the College of Chemistry, University of California Berkeley Calif , on ' Old and New Views of Acids ' , Dr George D Birkoff, the distinguished mathematician of Harvard University Cambridge, Mass , on "Electricity as a Fluid" Dr Forest Ray Moulton, permanent secretary of the American Association for the Advancement of Science, Washington, D C , on The Influence of Astronomy on Science , Dr Arthur L Day formerly director of the Geophysical Laboratory, Carnegie Institution, Washington D C on Volcanoes Geysers and Hot Springs" , Dr Louis Martin, director of the Pasteur Institute Paris, on L'Hospitalisation des Maladies Contagieuses Dr Thomas H Morgan, of the California Institute of Technology Pasadena, Calif , on ' Human Heredity and Modern Genetics" , and Dr Merritt L Fernald, of Harvard University, on Must All Rare Plants Suffer the Fate of *Franklinia* ?"

Lectures on applied science were given at the Franklin Institute on the following day by Dr Willis R Whitney, vice president in charge of research General Electric Company, Schenectady, N Y , who spoke on 'It's Called Electricity Dr Abel Wolman, professor of sanitary engineering, Johns Hopkins University, Baltimore Md , on ' The Trend of Civil Engineering since Benjamin Franklin ' , and Dr Harvey N Davis president of the Stevens Institute of Technology Hoboken, N J , on ' Engineering and Health'

Delegates from leading learned societies and educational institutions of the United States and Europe were welcomed at the dedication ceremony by Philip C Staples, president, and Dr Henry Butler Allen, secretary and director of the Franklin Institute Sir Albert Seward, delegate from the Royal Society of London, was in attendance with Lady Seward and presented to the Institute a photostat copy of the certificate making Franklin a fellow of the Royal Society in 1756

Artificial Production of Snow Crystals

IN NATURE of August 28, 1937, p 345, an account was given by G Seligman of experiments carried out at the University of Hokkaido by Prof U Nakaya Since that article was written, Prof Nakaya has made considerable progress towards his aim to produce, artificially and under strictly controllable conditions, the great variety of natural snow crystals[*] He assumes that we can trace the entire history of the fallen snow crystal from observations of its size, form and habit, and infer the physical state of its environment during condensation and during its subsequent movements through the atmosphere, if we can establish the laws governing its development.

---

[*] Preliminary Experiments on the Artificial Production of Snow Crystals By Ukitirô Nakaya, Isonosuke Satô and Yatarô Sekido Further Experiments on the Artificial Production of Snow Crystals By Ukitirô Nakaya Yasuaki Toda and Syûsô Maruyama (*J Fac Sci*, Hokkaido Univ , Series II, Vol. II, No 1, 1938)

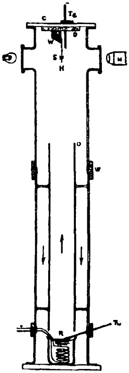


Fig 1
APPARATUS FOR THE ARTIFICIAL PRODUCTION OF SNOW CRYSTALS

Nakaya's experiments were carried out in a cold chamber the temperature of which could be lowered to −50° The apparatus employed for the production of artificial snow crystals is shown in Fig 1 By heating the water in the dish *R* with an electric coil, a flow of saturated, warm air is produced in the inner of two concentric cylinders When the air reaches the point *O* it is chilled by the walls of the cooled outer cylinder. The rabbit hair *H* serves as a nucleus for the condensation of the now supersaturated vapour and the growing crystal *S* can be observed through the telescope *M*. The temperature at the water surface (T_w) and that near the crystal (T_a) are recorded. The apparatus has the advantages that both the temperature and the degree of supersaturation can be varied within wide limits, and that a nucleus for the condensation is provided which allows unhampered growth of the crystal in all directions and yet keeps it stationary in front of the telescope. Fig 2*a* shows a snow crystal grown in this apparatus, still attached to the rabbit hair. It is seen from comparison with the natural snow crystals reproduced in Fig. 2*b* that the artificial product resembles the natural one in regularity as well as in degree of complexity.

Nakaya divides the growth of the snow crystal into two stages the formation of the germ and its subsequent development. He finds that the type of the former greatly influences the final shape of the crystal, however radically he alters T_w and T_a during the second stage Therefore, the first object of his investigations was an enumeration of possible types of germs and a study of the conditions for their formation Schematic drawings of his twelve types of early stage snow crystals are shown in Fig 3, and a record of their history is given in the table which follows Evidently temperatures above −20° C, with a relatively copious supply of water vapour, produce complex shapes such as dendrites or "assemblages of sectors", the latter probably caused by multiple twinning The formation of simpler types appears to be favoured by lower temperatures, while the perfection of the crystals seems to depend primarily on the regularity of the temperature gradient Rapid chilling of highly supersaturated vapour produces clusters of irregular fragments (Type 2) or even frozen droplets.

Fig 2.
SNOW CRYSTALS. (*a*) ARTIFICIAL CRYSTAL. × APPROX. 11. (*b*) NATURAL CRYSTAL. × APPROX. 12.

The actual degree of supersaturation in the neighbourhood of the rabbit hair was not measured in any of Nakaya's experiments, but a supersaturation ratio (s) is given, defined as the ratio of the saturation vapour pressure at the water surface (T_w) to that near the crystal (T_a). It was found, however, that experiments with identical supersaturation ratio did not always produce the same results, since uncontrollable factors such as deposition of hoar crystals on the walls of the cylinders influenced the concentration of moisture at the top of the apparatus. On the other hand, it was observed that the rate of growth, defined as the increase per hour in the diameter of a circle enclosing the crystal, is characteristic for each type and can serve as a qualitative measure of the degree of supersaturation. However, absolute measurements of the supersaturation values in terms of water content per unit volume seem highly desirable in view of the possible applications of Nakaya's researches to meteorology.

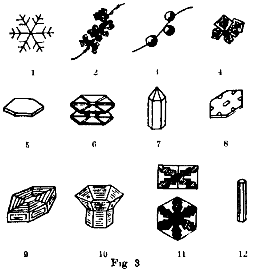

Fig 3

TWELVE TYPES OF SNOW CRYSTALS IN THEIR EARLY STAGES

1. Dendrite.
2. Clusters of irregular fragments.
3. Frozen droplets
4. Assemblages of sectors.
5. Thin hexagonal plate.
6. Cylinder with end plates.
7. Prismatic pyramid.
8. Hexagonal plate with design
9. Thick hexagonal plate.
10. Cup crystal.
11. Prismatic skeleton.
12. Prismatic needle

During the second stage of crystal development, the rates of growth have been measured with considerable accuracy Some of the results are given below :

Fern like dendritic branches of great complexity	10–3 mm. per hr.
More massive hexagonal plates with broad extensions at the corners	1·3 mm per hr
Hexagonal plates and assemblages of sectors of plates	0·7 mm. per hr.
Massive prisms, pyramids, prismatic needles* and 'spirals'	0·5 mm. per hr

The spirals are a peculiar phenomenon which has been observed in crevasse hoar by Seligman and others. They look like ordinary hexagonal prisms, but on closer inspection their cross-section perpendicular to the hexagonal axis is seen to resemble a 'hexagonal clock-spring'. Slow growth of the germ is essential for this type. In Nature, it develops only under calm conditions with a small temperature gradient providing for a slow rate of sublimation.

Nakaya also reports that rhombohedral (β-ice) and cubic ice crystals were produced at temperatures of about −30° C and low saturations. In view of the fact that neither X-rays nor polarized light were employed for their identification, these results must be regarded as rather uncertain Finally, snow crystals were grown from heavy water. It is interesting to note that their external structure was very similar to that of snow crystals grown from ordinary water

Nakaya has taken many thousands of photomicrographs of artificial snow crystals. By his elaborate researches he has created an invaluable new implement for the meteorologist and provided the research worker on snow with a most interesting collection of new facts It is to be hoped that by a more systematic presentation of his results, by improvement of his nomenclature along more accepted crystallographic lines and by quantitative measurement of his supersaturation values, he will justify the expectations of those who have followed his earlier work. **MAX PERUTZ.**

Type No	Type	T_w			T_a			t (in hours)
		Initial	Middle	Final	Initial	Middle	Final	
1	Small dendrite	+ 5° C	+ 10° C	+ 15° C	− 19° C	− 17° C	− 18° C	0·5
2	Clusters of irregular fragments	+ 3	+ 35	+ 20	− 20	− 13	− 15	0·5
3	Frozen droplets	+ 6	+ 46	+ 25	− 22	− 10	− 12	0·5
4	Assemblages of sectors	+ 10	+ 16	+ 19	− 15	− 13	− 12	1·5
5	Thin hexagonal plate	+ 6	+ 10	+ 12	− 24	− 22	− 16	2
6	Cylinder with end plates	0	+ 8	+ 20	− 20	− 20	− 14	5·5
7	Prismatic pyramid	+ 3	+ 5	+ 10	− 29	− 27	− 25	7
8	Hexagonal plate with design	+ 4	+ 4·5	+ 4·5	− 26	− 27	− 28	15
9	Thick hexagonal plate	+ 2	+ 4	+ 1	− 38	− 36	− 39	18
10	Cup crystal	+ 5	+ 4·5	+ 4	− 21	− 21	− 19	17
11	Prismatic skeleton	+ 6	+ 8	+ 10	− 22	− 22	− 20	20
12	Prismatic needle	+ 4	+ 4	+ 4	− 30	− 30	− 28	25

---

* In his article in NATURE, Mr Seligman expressed his surprise that Nakaya observed needles and prisms at different ends of the temperature scale in snowfalls, the needles occurring under warm and the prisms under extremely cold conditions It may be suggested that these needles are not prismatic, but consist of branches of dendrites which have broken off from their base and lost the details of their structure by melting

Obituary Notice

Prof A E Boycott, F R S

ARTHUR EDWIN BOYCOTT whose death occurred on May 12 last was an eminent pathologist He was also a distinguished naturalist He was listened to with the same respectful attention by an assembly of malacologists as by one of pathologists His wide knowledge of biology is notable in his writings and gave a special character to his teaching of pathology

Boycott was born at Hereford in 1877 and educated at the Cathedral School In 1894 he entered Oriel College Oxford, with an open classical scholarship He gained a first class in Classical Moderations and then turned to medicine pursuing his preliminary scientific studies in the Natural Science Schools He studied physiology under Burdon Sanderson Gotch Mann and Haldane and pathology under Ritchie He was particularly influenced by the last two both of whom became life long friends He graduated with first class honours in natural science and was elected to a Fraser Research Scholarship In October 1899 he went to St Thomas s Hospital where he completed his medical course and graduated M B (Oxon) in 1902

Boycott wanted to devote his life to investigation rather than to practice of the healing art and in the following year the first step towards satisfying this ambition was achieved by his appointment to a subsidiary lectureship in pathology at Guy s Hospital and election to a fellowship at Brasenose In 1904 he accepted the position of assistant bacteriologist at the Lister Institute Three years later he was recalled to Guy s to become the first whole time lecturer in pathology In 1912 the chair of pathology at Manchester became vacant and Boycott was appointed He liked the University but disliked the climate of Manchester and in 1915 he returned to London to occupy the Graham chair of pathology at University College, which carried with it the supervision of the research laboratory of the new clinical school Here he remained until 1935 when continued ill health obliged him to resign and retire to the country

Boycott s scientific activities covered a wide range His individual researches and those conducted in collaboration with various colleagues and pupils on physiological, pathological and zoological subjects are contained in some eighty papers, and it is impossible to do more than indicate the scope of some of the more important in a short article

The earliest work published by Boycott on the effect of cold on the conductivity of nerves in the frog and rabbit respectively was done under Gotch The publication of these two papers stamped him as a capable investigator, but he did not follow up this line of inquiry after leaving Oxford

In 1903 the co operation of Boycott was enlisted by his former teacher, John Haldane, in an investigation of the anæmia of Cornish miners Haldane had discovered that the trouble was due to ankylostomiasis a disease hitherto unrecognized in Britain Together they embarked upon a comprehensive research into this disease which continued by Boycott lasted some three years This investigation left not much unknown about its pathology its epidemiology in mines in Great Britain and the life history of the parasite

Whilst at the Lister Institute Boycott made a useful contribution to the immunology of typhoid and paratyphoid fevers and also a study of the seasonal distribution of the diphtheria bacillus and Hoffmann s pseudo diphtheria bacillus in the throats of a London population but he was mainly occupied with Haldane during this period with an extensive investigation of the effects of compressed and rarified air upon the animal body That on increased atmospheric pressures in which Damant also collaborated was called forth in order to explain and if possible to find means to prevent, the often fatal accidents to which caisson workers and deep sea divers are liable

Much valuable information was obtained about the pathology of compressed air illness It was shown to be due to the formation of bubbles of nitrogen in the tissues during the period of decompression if this were too hastily brought about The relationship between this occurrence to both the amount and duration of the compression and to the rate of decompression was determined experimentally The correctness of Haldane s prediction that if decompression were carried out by stages instead of continuously the time required for safety could be greatly reduced was also demonstrated and their experiments were sufficiently quantitative and numerous to permit time tables for decompressing divers by stages to be drawn up which afforded a margin of safety These are now universally employed Incidentally the working time under pressure and the depth attainable by divers has thereby been materially increased The investigation by Haldane and Boycott of the regulation of respiration at reduced atmospheric pressure and of the pathology of mountain sickness, in which Ogier Ward was a partner was also a fine piece of work The results furnished a completer understanding of the causes of the respiratory embarrassment when the tension of oxygen is reduced by rarefication of the air and of the body's methods of acclimatization to high altitudes

Boycott was engaged in yet another research with Haldane on the physiological adaptation of man to an environment of high temperature and great humidity in which the limitations of adjustment were ascertained both when idle and performing increasing amounts of work They published only one short paper together on this subject , the bulk of the observations for which Boycott was responsible were incorporated in reports and lectures by Haldane

The contribution to the above three researches made by Boycott has been somewhat obscured by the fame of the senior partner Haldane originated them and doubtless had much say in the planning of the experiments, but Boycott had most to do with carrying them out

Boycott s scientific output during the three years spent at the Lister Institute was very considerable The partnership with Haldane was a delight, and mutually advantageous Boycott was young and vigorous, and had neither teaching nor administrative duties Henceforth, he occupied professorial posts, and responsibility for the pathology of great hospitals teaching, the direction of the work of others and the editorship of the principal pathological journal in Britain greatly reduced the time left for individual researches Nevertheless he continued to be an active experimenter

From 1908 onwards a great part of Boycott s researches, in most of which various colleagues collaborated, was concerned with some aspect of blood as a tissue Whilst a student at Oxford, he had become an adept with the method of Haldane and Lorrain Smith for determining the total volume of blood in the body Years afterwards, he and Douglas critically re examined the method and showed that with minor improvements in technique reliable results could be obtained and that in skilled hands it was free from danger Boycott afterwards made good use of this powerful engine of research in investigating various types of anæmia and polycythemia occurring in patients and experimentally produced in animals These have led to a clearer conception of the pathological features of these diseases

A subject which especially aroused Boycott s interest and to the investigation of which he returned again and again was the power possessed by the body to restore the volume and composition of the blood to normal after disturbance by hæmorrhage or transfusion Some of his best work is that designed to throw light on the way these reparative adjustments are brought about He found that the rate of restoration was increased by education and that the destruction of superabundant elements after a transfusion only occurred if they were not wanted He discovered a number of interesting facts and, although complete understanding of how such adjustments are brought about is still far off, these facts and the emphasis he laid upon them are highly important

Another experimental inquiry which was begun at Guy's with Ryffel and continued at Manchester with Douglas as partner had for its purpose the study of the part played by the kidney in the regulation of the volume and composition of the blood With this object, Boycott and his colleague studied the effects of withdrawal and addition of fluids and the action of diuretics on normal animals and others in which the secretory tubules of the kidney had been put out of action by poisoning with salts of uranium Adjustment was found to be much delayed in the latter The interpretation of some of their experimental results was not clear at the time, but later work by others has afforded an explanation of some of them

Boycott was distinguished from other prominent hæmatologists in that he was interested in blood as a whole and not more particularly in its cellular constituents His discoveries constituted an important contribution from several angles to the physiology and pathology of blood Many of them were incorporated into the excellent article on the subject written for Pembrey and Ritchie's "Text Book of General Pathology" in 1913 That is still good reading

During the earlier years of the Great War, Boycott was occupied in doing the work of younger colleagues who had joined the army He served upon various Government committees for which his special knowledge and sound judgment rendered him suitable It was an unhappy time as he found himself out of sympathy with the attitude of many of his friends towards the conflict In 1917 he joined the R A M C and was associated with Barcroft and other physiologists at the experimental station at Porton in the investigation of the physiological action of poisonous gases used or likely to be used by the combatants In this work he rendered valuable service, and its scientific interest mitigated the misery he endured in the contemplation of the purposes to which the materials were being put

As assistant editor of the *Journal of Pathology* for fifteen, and editor for twelve years, Boycott rendered a great service to pathology in Great Britain He was peculiarly well fitted for the work by his wide knowledge, critical judgment and keen appreciation of orderly presentation and literary form It was a labour of love and he devoted much of his time to the work He was a helpful editor, and many an author has to thank him for reducing his manuscript to readable shape, a process which sometimes meant re writing it The debt which the Pathological Society owes to Boycott will not easily be forgotten Under his editorship, its journal increased in prestige as well as in size

The briefest account of Boycott s scientific work would be inadequate without reference to his observations on snails As a boy he was fond of snails and catalogued those of Herefordshire The attachment lasted through life, and the last scientific papers he published were two memoirs on the habitats of the land and freshwater Mollusca in Britain These are not mere catalogues of distribution, they are full of information about the habits and life history of these creatures in so far as it appears to have determined their distribution A zoologist friend tells me they are regarded as classics, and that they contain more information to the page than anything he has read

Boycott is also responsible for a serious research in genetics It began some twenty years ago when his attention was directed to the occurrence of some left handed staircases in the shells of a common water snail, *Limnæus peregra*, in a pond in Yorkshire, and is still going on Usually dextral, the nature of its spiral depends upon the asymmetry of its soft parts. Boycott perceived that he had encountered first rate material for genetic research, the character, sinistrality, being readily discernible and no intermediate condition possible Furthermore, *Limnæus peregra*, although preferring cross fertilization, could readily be induced to propagate parthenogenetically He forthwith began to breed snails from selected parents or parent and to determine the proportion of right and left handed ones in successive generations As the generations increased and notwithstanding the enlistment of collaborators, the labour became almost overwhelming A few years ago the total progeny exceeded a million ! The results of this prodigious experiment were communicated from time to time in appropriate journals and in 1930 gathered together in a memoir published by the Royal Society in its *Philosophical Transactions* Briefly stated, sinistrality was found to be a Mendelian recessive character complicated by a tendency towards dextral mutations

The transfer of so much of Boycott's energy to zoology was regretted by his brother pathologists, and the fact that his love for biology was responsible for his wide outlook on pathology did not appease their jealousy

As well as being a fine experimenter, Boycott was equally good at contemplation and an artist in expression Of recent years he gave several stimulating addresses which have more than ephemeral value In these essays he found an opportunity for displaying the rare combination of knowledge, philosophical insight and literary charm which he possessed He used them to review knowledge of some subject in pathology and its implications, or for an expression of his views on the proper attitude towards the study of pathology His conception of the content of pathology was different from that of most He defined it as the study of how organisms resist and repair injury In the post mortem room and the museum are recorded only the failures on which he thought, attention had been too much concentrated The phenomena of protection and repair certainly represent the more cheerful side of pathology and were particularly attractive to Boycott because of the evidence of purpose apparent in them

Boycott was one of those who are said to pursue knowledge for its own sake which means that he was curious and found sufficient satisfaction in making experiments with a sporting chance that he might have imagined the right question to ask and planned the appropriate experiment to obtain an answer Whether the knowledge to be gained was likely to be of any immediate service, ought, he maintained to be immaterial The exclusion of utility as a righteous motive for embarking upon an investigation was, I believe largely a reaction to the commercialism which he feared was trespassing upon the sanctity of scientific laboratories

He was a charming companion and a staunch friend always ready with help and sympathy in time of trouble He held strong views on most subjects and refused to compromise even on small matters when he imagined a principle was involved, but as he could be depended upon to be on the side of the angels, a measure of intransigence was unimportant

News and Views

Long-Range Weather Forecasts

In a series of questions asked by Mr S F Markham in the House of Commons on June 22, relating to the stations and research staff of the Meteorological Office, one referred to weather forecasts for a fortnight or longer, now being published in Great Britain and in Germany, and suggested that the Office might supplement its present forecasts by such long range predictions In his reply, the Secretary of State for Air said "I am aware of the long range weather forecasts being attempted by various methods in many different countries These efforts are being carefully studied by the Meteorological Office, but so far none of the methods has attained the accuracy which would justify the issue of such forecasts in this country" This reply may not satisfy the public, which fails entirely to distinguish between weather forecasts based upon established scientific principles and observations, from prophecies of an astrological nature or any system which has not been submitted to a scientific society for disinterested consideration Whatever is known about long range weather forecasting is understood by our Meteorological Office, and if any practical end could be served by applying such knowledge, advantage would certainly be taken of the opportunity. In science it is not enough for an observer to satisfy himself that his investigations prove a principle, but the evidence has to convince other scientific workers before the principle is accepted. Until this has been done, any long range weather forecasts published in the daily Press, whatever accuracy is claimed for them, are altogether unworthy of being placed in the same category as the daily forecasts at present issued

Air Survey and Archæology in Germany

Early in the current year, Mr O G S Crawford, archæological officer of the Ordnance Survey, received an official invitation from Germany to organize an exhibition of the results of archæological air photography in Great Britain, and to deliver a lecture on the subject in March An account of the exhibition is contributed by Mr Crawford to *Antiquity* of June 1938 With the consent of the Ordnance Survey, about forty enlarged, and about one hundred small photographs were shown, together with a selection from the remarkable collection of photographs taken by Major Allen, which Mr Crawford remarks, "so brilliantly illustrates the archæological value of air photography The exhibition was held in what was the Upper House of the former Prussian Parliament, the arrangements being made by the Lilienthal gesellschaft, and invitations sent to pilots of the German Air Force and to the leading German archæologists. The exhibition also included a selection of photographs taken by German pilots, who are now keenly interested in the subject and have begun to collaborate with the archæologists. It would appear that the exhibition, which lasted for two days, and of which the proceedings were devoted to the discussion of technical problems, was a great success. The meeting closed with a lecture by Mr. Crawford, when Dr. Buttler and Ministerialrat Ewald were present and also spoke. To this lecture members of the public were admitted, and several hundreds of people were present. An account of the proceedings is to be published by Lufthansa as an illustrated monograph.

AT the conclusion of the meeting, Mr. Crawford, in proceeding by air to Athens on business connected with the Greek portion of the map of the Roman Empire, was able to make a number of interesting observations. On his way to Berlin he had observed traces of an early, probably medieval field system between Brussels and Cologne, of which he had also detected indications on some of the German air photographs. Similar evidence was obtained in the soil marks—long white bands forming a pattern—between Budapest and Belgrade. These, in his opinion, are the vestiges of an ancient field system. Whatever their age and original intent, they seem to have no relation to the existing field system, which itself has the appearance of considerable antiquity. To decide the point, a large area should be photographed from the air in suitable conditions, and a mosaic constructed with subsequent excavation at selected points to decide the matter. In addition Mr. Crawford observed three Roman camps on arable land and the course of several defensive dykes, some of post-Roman date, which though long known to exist have never been properly investigated. Mr. Crawford concludes by pointing out that this region is one of the best fields in Europe for combined field work from the air and on the ground, and expresses the hope that our archæological colleagues of Yugoslavia will follow the example of Germany and inaugurate work in this unexplored and most promising field.

Excavations in the Egyptian Sudan, 1937-8

THE annual exhibition of the Egypt Exploration Society opened at the Society's rooms, 2 Hinde Street, Manchester Square, London, W.1, on June 23. It will remain open daily until July 14. In 1937–38 excavation was continued on the site of the fortress town of Sesebi on the banks of the Nile, about one hundred and eighty miles south of Wady Halfa. Shortly before the close of the season, the site had been completely excavated, and the expedition spent twelve days in a preliminary examination of the new concession at Amarah West, about sixty miles north of Sesebi, where it is hoped to begin systematic excavation in 1938–39. Although the number of finds at Sesebi this year was small, they are of no little archæological and historical interest. Faience objects bearing the name of Amenhotep IV from intact foundation deposits under the walls of the town indicate that the town, as well as the temple, was built by this king about 1480 B.C., before he adopted Aten worship and changed his name to Akhenaten. A sandstone block bearing a representation of the god Amun, or of Amenhotep wearing the plumes of the god, which was found built upside down in the sanctuary of the temple erected by Seti I, is of no less interest as an example of the art of the period before Akhenaten changed the canons of art, as well as his religion. Both these finds are of importance as belonging to a period from which material is scanty. A black granite fragment showing a daughter of the king, embraced by a sister or a parent, is the only clearly Amarna piece that has been discovered at Sesebi. An interesting sandstone bust of a dead man, swathed in mummy bands, which when in position would appear to be bursting from the ground, is a rare example of a symbol of resurrection.

THE most interesting and significant fact which emerges from the excavation at Sesebi is that though built in the conventional form of a fortress town, it had no moat, no special defences for its gates, and there was, apparently, no strategic reason for its position. It could not withstand a prolonged attack, whereas other previously known fortress towns of this region command strategic points on the Sudanese trade routes, have deep moats, and are strongly fortified. Hence it would appear that by the time Sesebi was built the political and economic dominance of the Egyptian Empire in the Sudan was sufficiently firmly established to make the establishment of fortress towns like Sesebi as anything more than trade and religious centres superfluous—an important piece of evidence of the organization of the Egyptian Empire in the Eighteenth and Nineteenth Dynasties. At Amarah West there has come to light in the preliminary tests evidence which suggests that there may have been a late Eighteenth Dynasty occupation as well as that of the Nineteenth, of which the remains, in the form of temple and town, crown the mound of the site under a deposit of some six feet of blown sand. This deposit has kept the walls in an excellent state of preservation, to a height of six feet, and holds out promise of inscriptional material, and possibly statuary, in the temple. An interesting find, of which it is hoped more will be heard in future excavation, is an axe celt and two agate arrow heads, which appear to afford evidence here of a new and little known Sudanese culture.

Exhibition of History of Handwriting

AN exhibition now open at the London County Council's Horniman Museum, Forest Hill, London, S.E., illustrates the development of handwriting and its different systems. It begins with pictographic and hieroglyphic forms, and shows how the conventionalized breaking down of the picture produced the alphabetic systems, tracing the development through early Phœnician to Greek and Latin. The development of Babylonian cuneiform is also shown, demonstrating how its character was determined by the nature of the material used for record, the clay tablet, which necessitated the use of a stylus in the form of a stamp lending itself to ready and relatively rapid duplication. Among later developments shown are the Lombardic, Merovingian, Visigothic, Anglo-Saxon and Irish 'hands', as well as the still later and contrasting forms of Italian and English Secretary—Shakespeare's signature is an example of the latter—between which rivalry lasted in England until well into the seventeenth century. The exhibits include illuminated manuscripts, samplers and tally sticks, facsimiles of important historical documents, such as Magna Charta, and of the signatures of prominent personages, ancient and modern. The exhibition will remain open until August 31.

"Druid" Temple near Glasgow

A LARGE part of this temple on the Anniesland-Duntocher Boulevard at Glasgow, near Clydebank and Kilbowie, has now been re-constructed. New wood has been substituted for the decayed and carbonized original timber. The circular area of the sanctuary appears to have a diameter of 245 feet, bounded probably by a ring of nineteen large, white, hard sandstone pillars equidistantly set and each about 8 feet in height. Numerous graves have been found under the floor or old surface. As indicated by the pottery and other relics, the burials near the centre are of the Stone Age. The outer graves belong to later prehistoric periods, the various phases of the Bronze Age. The temple was evidently a favourite place for interments for a very long period. Four graves, very close to the centre of the temple, have just been opened and may be inspected during the next few days, after which they will be again covered over. These four graves are all built of large stones and in two cases contain much decayed timber and wicker work. The topmost stones in several cases bear curious devices belonging to the class of carvings known as 'cups and rings'. Stone implements were found in some of the tombs. The largest of the four tombs has a depth of 8 feet. The walling of its shaft contains about fifty stones. The excavation of this site has been carried out by Mr. Ludovic Mann, 183 West George Street, Glasgow, C 2.

New Pathological Institute at Guy's

THE new Pathological Institute of Guy's Hospital Medical School was opened on June 23, by the chancellor of the University of London, the Earl of Athlone, supported by the vice-chancellor, Sir Robert Pickard, and the principal, Dr. H. L. Eason. The Governing Body was represented by Viscount Goschen, Viscount Nuffield, Lord Cunliffe, and Mr. R. C. Nesbitt. The building is a large eight-story fire-proof extension behind the present anatomy, physiology and chemistry departments on a site formerly occupied by Spur Inn Yard, the outbuildings of a famous medieval Southwark inn. It combines in a single unit the former scattered laboratories of pathology, clinical chemistry and bacteriology, originally housed in old adapted warehouses. Ample laboratory accommodation is also provided for the Clinical Research Unit recently established by the Medical Research Council at Guy's and for the Guy's Hospital clinical research fellow. The connexion between the Medical School and the Hospital will be fully maintained by the provision of extensive accommodation for the hospital routine investigations. Thirty fully equipped laboratories have been provided for original investigations. The total cost of the building and equipment has been between £85,000 and £90,000, of which £10,000 has been contributed in the form of a capital grant by the University Court. There remains a debt of some £40,000, which, until paid off, will prevent the full realization of the objects for which the building has been provided.

The Newcomen Society

FAVOURED with beautiful weather the Newcomen Society held its summer meeting in the Lake District on June 15-18. The programme was a very full one and included visits to mines, iron furnaces, snuff mills, an organ building works, a bobbin mill, a paper mill and Kendal Museum. At Lindale in Cartmel a short stay was made to inspect the cast iron obelisk to the memory of the great iron master John Wilkinson, and in a small engineering shop near Kendal the members found a very early iron planing machine, which it is to be hoped will one day find a place in a museum, instead of passing to the scrap heap. With its many streams, the Lake District abounds in turbines and water wheels several of which are of considerable interest. Not the least interesting items in the programme were the visits to the Greenside Lead Mines, Glenridding, which, after being worked for two hundred years, are being modernized, and to the old copper mine at Goldscope, a short way from Keswick, which was worked in the days of Queen Elizabeth by the Society for the Mines Royal. At a meeting on the evening of June 15, a paper was read on the works at Goldscope, by Mr. Rhys Jenkins, who has traced the immigration into the district of some 150–200 German miners from the Tyrol. The principal figure in the venture was Daniel Hochstetter, while much of the capital was provided by the Augsburg firm, Haug and Co., the account books of which are still preserved.

The Dartmoor Catchments

AMONG the papers presented at the annual general meeting of the British Waterworks Association on June 22 were two containing certain features of general scientific interest. The paper on "The Dartmoor Catchments" by Mr. Hansford Worth gave a detailed description of the physical features of the great granite highland occupying an area of 248 square miles in the county of Devon. He divided it into three districts, the eastern, the northern and the southern, according to differences of elevation. He explained how the weathering of the granite results in a product, locally known as 'Growan'. Owing to the softening of the rock and the loss of its coherence as the result of the decay of the felspars, there is evolved a sandy, and not a clayey mass, which, near the surface, shows the movement known as 'hill-creep', an excellent example of which is to be seen on the roadside near the Sheepstor Dam The porosity of the growan affords ample storage for rainfall, which in Devon is high, ranging up to more than 80 inches per annum The monthly distribution is remarkably regular, when long periods are averaged, but wholly irregular in any one year Mr Worth went on to analyse the run off resulting from rainfall and found that there is a drought regime for every stream, and that following any day in which there has been no actual flood, it is possible from the ascertained flow on that day accurately to predict the flow of the stream for the next 24 hours, in the absence of rain Instances were given of several notable floods and their havoc

Protection of Underground Water Supplies

THE second paper, on The Protection of Underground Sources of Water Supply ', by Mr Edgar Morton, had special reference to the Town and Country Planning Acts, and was directed to two aspects of protection, namely, protection of an existing source of public supply against exploitation for industrial purposes, and, secondly, protection against the possibility of pollution from external sources As regards the former, pointing out that in most private Acts involving underground waterworks, there is a clause for the protection of existing sources of supply—wells, boreholes and springs—within a specified radius of the authorized works, Mr Norton stated that within recent years there has been a tendency to extend such protection to include streams, ponds and pools, in so far as they are fed by springs which originate within the protected zone, although the user of such streams, ponds or pools may be outside the zone A serious aspect of the inadequacy of existing legislation is that, while Parliament imposes upon the promoters seeking new sources of supply for public benefit at the least possible cost, restrictions respecting their boreholes, no reciprocal protection has until recently been given to the promoters against the exploitation of their water resources by industrial enterprise As regards protection against pollution, various ways were enumerated by which it could be obtained in limestone and chalk areas and in sandstone areas respectively, with instances of specific cases

The Argyll National Forest Park

REFERENCE to the Argyll National Forest Park was made in NATURE of October 16, 1937, p 692, and now a small brochure with the title "The Argyll National Forest Park Guide ' has recently been issued by the Forestry Commissioners The Guide has been edited by Prof John Walton, regius professor of botany in the University of Glasgow, and has a foreword by Sir Roy Robinson, chairman of the Forestry Commission The National Park consists of large stretches of mountain and moorland lying to the west of Loch Long It is divided into two main areas. The northern consists of Ardgartan and Ardgoil and forms a wedge of mountains between Loch Goil and Loch Long The southern area is bounded on the east by Loch Long and Loch Goil The two areas are built up of a group of estates, the Ardgoil Estate having been presented to the Corporation of the City of Glasgow by Mr Cameron Corbett, the others having been acquired by the Forestry Commission, which has since afforested large areas The total area of the estates amounts to 54,000 acres about 19,000 of which are reserved for afforestation, leaving approximately 35,000 acres available for use as a National Park At the southern end of this Park are situated Benmore House and its finely laid out gardens and shrubberies which were presented to the Forestry Commissioners by Mr Harry G Younger This Park presents interests for every taste and the Guide deals with its history (Prof J D Mackie) geological structure (Dr J G C Anderson), vegetation (Prof J Walton), forests and plantations (Mr J M Murray, assistant commissioner for Scotland), and fauna (Prof E Hindle), all, with the exception of Mr Murray, on the staff of the University of Glasgow

British Museum (Natural History). Acquisitions

AMONG recent additions to the zoological collections is the skull of a swamp deer (*Rucervus duvauceli*) from India presented by Mr D H Keelan The specimen is remarkable for the symmetry of the antlers A collection of mammals formed by the late Captain H D Hilton Simpson has been presented by Mrs Hilton Simpson, included in this series is a mounted head and a skull of a race of buffalo named by the late Richard Lydekker after Captain Hilton Simpson, *Syncerus caffer simpsoni* A number of mammals from Kenya Colony, including a specimen of a rare crested bush rat, *Lophiomys testudo*, and twenty small mammals from Sierra Leone are the gifts respectively of Colonel C H Stockley and Mr R R Glanville An 'ivory pearl from the tusk of a Uganda elephant has been presented by Mr Q O Grogan This concretion is an especially large one and shaped rather like a small potato Among recent donations received from the Rowland Ward Trustees is an African tiger cat, *Felis celidogaster*, mounted for the galleries, and the skull of an African dwarf buffalo A splendid group of slender prisms of stibnite (antimony sulphide) and another specimen of baryte on stibnite from Baia Sprie, Rumania, are the most interesting of the purchases made for the Department of Mineralogy The Geological Survey of India has presented to the same Department three samples of different grades of diamondiferous gravel from the Karnool District, Madras Presidency Diamonds in this district are obtained from alluvial deposits and also from a conglomerate at the base of the Karnool Series among rocks of Precambrian age These gravels have been presented in response to a request for specimens to illustrate the modes of occurrence of diamond, which is the subject of the first section of the diamond case (near entrance to the Mineral Gallery) recently rearranged

THE Department of Botany has purchased about 700 drawings and some manuscript of J J Dillenius, the first Sherardian professor of botany at Oxford In 1719, Dillenius published his "Catalogus Plantarum

Science in the Seventeenth Century*

By Prof. E. N. da C. Andrade, F.R.S.

THE AUTHORITY OF ARISTOTLE

THE sixteenth century was a period of reference to written authority, and in science the supreme rulers were Aristotle in all that pertained to the exact sciences and to general biology, and Galen in all that pertained to medicine. Occasionally a doubter arose, such as Paracelsus, only to be, at best, overwhelmed with ridicule and contempt, or, at worst, more drastically suppressed, as exemplified by the case of Giordano Bruno, who was burnt in 1600. The opinion widely expressed was that the world, Nature and particularly the human intellect, were in process of decay which had set in since the glorious times of classical Greece: it was seriously contended that the great minds of antiquity represented a race of giants which had died out just as the race of physical giants had died out. In particular, the works of Aristotle were supposed to fix the limits to which the human intelligence could reach, and the obvious thing to do, when seeking information as to the way in which Nature worked, was to refer to these works.

The method of Aristotle was, of course, speculative. Starting with certain philosophical ideas as to the nature of matter, derived partly by direct apprehension, partly by reasoning from a few observed facts of Nature, such as the circular motion of the stars, he proceeded by logical processes to argue how Nature should behave in order to conform with his innate ideas as to harmony and balance. This is no place to discuss the Aristotelian doctrine of form, which exercised so profound an influence on those who came after him, but it is necessary for our purpose to refer briefly to his ideas on motion and mechanics in general. He made a clear distinction between natural motion and violent, or artificial, motion. From the motion of the heavens he concluded that motion in circles was a natural motion. From the spontaneous motion of dropped bodies downwards, and of smoke and fire upwards, he concluded that a vertical motion was also a natural motion, adding to the idea of gravity downwards that of levity upwards. The four elements, earth, fire, air, and water played an essential part in the Aristotelian scheme; earth and water strove downwards, air and fire upwards.

The motion of a projectile or any propelled body, was a violent, or non-natural, motion. His fundamental error in considering these non-natural motions lay in his belief that bodies only moved so long as a force was acting upon them; he supposed that a thrown body continued in motion after it left the hand only because the moved air beat on it behind and carried it forward. It may be pointed out that this was an idealization, not an observed fact. A body set in motion by a force is observed ultimately to come to rest, he supposed that it would come to rest at once if the force ceased at once, but that the action of the force was continued by the air, ultimately dying out. Another idealization of the observed fact is to suppose that a body set in motion would continue to move, after the force had ceased to act, with a uniform velocity for

SANTBECH'S CONCEPTION OF THE TRAJECTORY OF A PROJECTILE, MODUS VIOLENTUS AND MODUS NATURALIS

ever, were it not that adventitious forces, such as friction, act upon it, and ultimately bring it to rest The latter is Galileo and Newton's idealization, which now lies at the basis of our mechanics Neither of the two is inherently more probable than the other, only experiment and observation have convinced us that the modern view is the scientifically correct one

As regards fall in particular, Aristotle considered that a moving body was acted upon by a power moving it and by a resistance if power and resistance were equal the body did not move This is a fundamental mistake It was argued by others (but apparently not explicitly by him) from his fundamental conceptions that the time of fall of a body was inversely as its weight. Experiment had no part in his scheme, probably because he was dealing with first causes, and isolated material phenomena he held to be without fundamental significance. Form was more important than matter. We see something of his point of view in the works of certain modern economists, who regard actual economic events as of little significance.

How profound was the influence of Aristotelian mechanics in the sixteenth century, even in discussion of practical matters, is well exemplified in Santbech's discussion of the motion of projectiles, published in 1561 He states that the motion of a projectile consists of an oblique violent motion which suddenly ceases, and is succeeded by a natural motion of vertical fall. He gives diagrams (of which Fig 1 is an example) showing the path of a cannon ball as two sides of a right-angled triangle, the hypotenuse representing the violent motion, and the vertical side representing the vertical fall on to the object aimed at On this basis he proceeds to solve problems in ballistics Other writers of about this time, apparently feeling uneasy about the sharp angle at the highest point of the trajectory, replaced it by a circular arc joining the straight-line oblique motion to the straight-line natural fall, the motion in this arc being a mixed mode, so that the whole trajectory consists of a straight line *modus violentus*, a curved *modus mixtus*, and a straight vertical *modus naturalis* (Fig 2). It is a strange comment on the way in which these writers refused to let observation influence them that in a book by Rivius, published in 1547, the discussion of ballistics is carried out in terms of trajectories of this kind,

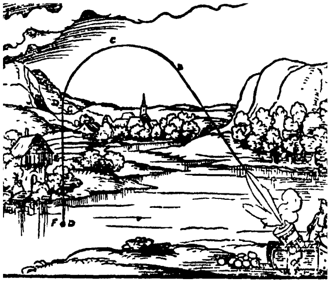

Fig. 2.
MODUS VIOLENTUS, MODUS MIXTUS AND MODUS NATURALIS

while in pictures in the same book, in which the artist shows the bombardment of a town, the trajectories of the bombs are shown as tolerably correct representations of the path of a real projectile

Let us look at the position at the opening of the seventeenth century Copernicus had published his "De Revolutionibus" in 1543, when he was on his death-bed, but the astronomers who followed him were divided in their attitude towards his theory Giordano Bruno, who upheld the Copernican hypothesis, was burnt in 1600 , Rheticus, Reinhold and Mästlin contended for the theory , not only Luther and Melanchthon, but also the great observer Tycho Brahe, who died in 1601, pronounced against it Kepler (1571–1630) was, on the other hand, a Copernican He had published his "Prodromus" in 1596, in which book he traced a mystical connexion between the distances of the planets, and the radii of six concentric spheres, between which the five regular solids were fitted. This was, of course, in the spirit of Pythagoras, who saw in the heavens a mysterious harmony which could be expressed in numbers.

Kepler's famous laws were not published until the century had well started, the first and second in the "Astronomia Nova", 1609, and the third in the "Harmonices Mundi", 1619 These laws gave the geometrical form of the planetary orbit, and a time-table for their progress in these orbits, but envisaged no quantitative mechanism to account for that form and that timetable At the beginning of the century he considered that planets must have some kind of souls to urge them on in their paths, but later he resorted to a magnetic influence emanating from the sun, of a kind, however, that did not in any way correspond to the laws of magnetism as we know them, for he supposed that it was the rotation of the sun on its axis that was responsible for the urge His great difficulty in the way of mechanics was that he had no conception of inertia Of mutual gravitation he had, however, some idea, and even explained the tides as due to an attraction of the moon for the waters of the earth Probably his magnetic hypothesis was due to Gilbert's book, "De Magnete", the appearance of which in 1600 aptly inaugurated the century which saw the triumph of the experimental method

THE MECHANICS OF GALILEO

The first great name with which we have to deal, if we wish to trace the rise of modern mechanics, is Galileo, who was born in 1564, the year in which Michelangelo died Everybody knows the legend that, as a young man in Pisa, he confuted the Aristotelians by letting spheres of different masses fall from the tower of Pisa, and observing that they all took the same time to reach the ground—a legend, because the indefatigable researches of Wohlwill have shown that it is highly improbable that he ever carried out this experiment The story that he did so is due to Viviani, who published his book in 1654, twelve years after Galileo's death, and who first met Galileo towards the end of his life Galileo was in Pisa from the seventeenth to the twenty-eighth year of his age, and there seems no doubt, that, as we should expect, when he first began to lecture he believed what he had been taught, and was a devout Aristotelian The experiment which he actually carried out was to let fall a lead and a wooden sphere, and what he noted was that the wood fell more quickly at first, but that later on the lead overtook it, and reached the ground first ! He was at the time too much of an Aristotelian to attach much importance to this finding that, of two bodies of equal size, the heavier fell slower at first but afterwards quicker[*]

Later he turned against the pseudo-Aristotelian belief that the rate of fall was proportional to the weight This was not due to experiment, but to an appeal as to what was reasonable He says "If we let two stones fall from a high tower, one twice as big as the other, it is ridiculous to suppose that when the big one has reached the ground, the other will be only half way down", but he adds "we will work more with reasoning than with examples, for what we seek is the cause of phenomena, which experience does not provide", a very Aristotelian sentiment. It was not until later that he showed that genius for experiment which is one of his great claims to fame In short, he did not suddenly, as a young man, reject the whole body of knowledge in which he had been brought up, but he gradually freed himself from the scholastic point of view, and laid the foundations of modern science

In popular estimation, Galileo is, perhaps, best known as the man who first turned the telescope to the serious study of the heavens—in fact he is often attributed with the discovery of the telescope although actually what happened was that having heard that such an instrument had been made in Holland he himself made one without being supplied with details as to the method of construction His observations were of the first importance The discovery of the mountains of the moon struck the popular fancy It is the one point to which Milton who visited Galileo in his old age refers in Paradise Lost

---

[*] The question of the supposed experiment at Pisa is discussed in a very scholarly manner by Prof Lane Cooper in a little book "Aristotle, Galileo and the Tower of Pisa", which has come to my notice since this discourse was delivered. The learned author, who is professor of the English language and literature in Cornell University, sets an example to some of his scientific brethren who write on such matters, by his constant reference to the original sources. I am glad to find that his conclusions support what is written above

> his pond rous shield
> Ethereal temper massy large and round
> Behind him cast the broad circumference
> Hung on his shoulders like the Moon whose Orb
> Through Optic Glass the *Tuscan* Artist views
> At Ev ning from the top of *Fesolé*
> Or in *Valdarno* to descry new Lands
> Rivers or Mountains on her spotty Globe

The lunar landscape at once suggested that the moon might be inhabited as discussed for example in Wilkins The Discovery of a World in the Moone (1638) The discovery of the phases of Venus established the rotation of that planet round the sun and as a matter of fact the fact that they were not observed with the naked eye had been recognized as a difficulty by Copernicus who explained it away by suggesting that Venus was transparent In the discovery of sunspots which was a blow for the Aristotelians since it showed that the eye of the world was not perfect he was anticipated by Fabricius He observed that the Milky Way consisted of innumerable stars As regards Saturn owing to the position of the rings and the imperfect resolution of his telescope he concluded that the planet was accompanied by two satellites practically touching it or as he said I have observed the planet Saturn to be triple — *altissimum planetam tergeminum observavi*

Probably the most important discovery which Galileo announced in his Siderius Nuntius or Messenger from the Stars was the existence of the satellites of Jupiter which revolving round the planet gave a picture of the Copernican system His astronomical discoveries then form an imposing collection but Lagrange whose opinion on anything that pertains to the science of mechanics must carry immense weight makes light of them in comparison with Galileo s services as the founder of the science of mechanics Les découvertes des satellites de Jupiter des phases de Vénus des taches du Soleil etc ne demandaient que des télescopes et de l assiduité mais il fallait un génie extraordinaire pour démêler les lois de la nature dans des phénomènes que l on avait toujours eus sous les yeux mais dont l explication avait néanmoins toujours échappe aux recherches des philosophes Although we may not agree that anyone with a telescope—especially such a telescope as Galileo possessed—and industry could have made his astronomical discoveries yet there is no doubt that the way in which Galileo made mechanics into a science is a most striking testimony to his genius

The great book in which he announced his fundamental discoveries in mechanics Discorsi e dimostrazioni matematiche intorno a due nuove scienze appeared in 1638 In it he established the law of fall and the parabolic motion of a projectile in a non resisting medium He deduced the law of fall from the supposition that there were equal increments of velocity in equal small intervals of time in the course of his arguments he considered any time interval as capable of being divided into an infinite number of instants and so foreshadowed the differential method He did not however connect a uniform acceleration with a uniform force but apparently attributed the increase in velocity to an increase in force during the fall and further he did not think of the fall as due to the attraction of the earth but rather to some urge inherent in the body As to the true cause of the acceleration however he expresses the same kind of reticence as was shown by Newton concerning the nature of the gravitational force We may take for example Salviati s speech on the third day of the dialogues The present does not seem to be the proper time to investigate the causes of the acceleration of natural motions concerning which various opinions have been expressed by various philosophers some explaining it by attraction to the centre others by repulsion between the very small parts of the body whilst others attribute it to a certain stress in the surrounding medium which closes in behind the falling body and drives it from one of its positions to another which fantasies and others like them create problems requiring examination but there would be little gain were they solved At present it is the purpose of our author merely to investigate and to demonstrate some of the properties of accelerated motion whatever the cause of the acceleration may be

Galileo perfectly understood inertia in the case of horizontal travel and used the fact that in the absence of horizontal force a body travels horizontally with a uniform speed in his investigation of the path of a projectile It is strange then, that he seems to have no conception of inertia in the case of the vertical motion of free fall. It has been suggested that this is possibly a relic of his Aristotelian training, a horizontal motion in the direction of the earth's surface, that is, in a very large circle, being a perfect motion, like that of the heavenly bodies There seems no need, however, to resort to this supposition , an accelerated motion is clearly harder to bring into any scheme than a uniform translation, as is sufficiently shown by the history of Einstein's theory of relativity. In any event, assuming equal increments of velocity in equal elements of time, he found, by what is essentially graphical integration, that the space traversed was proportional to the square of the time

He verified this law experimentally by measuring the time taken by a body rolling on an inclined plane to traverse various distances, measuring the time by a water clock, and "in such experiments, repeated a full hundred times, we always found that the spaces traversed were to each other as the squares of the times, and this was true for all inclinations of the plane along which we rolled the ball. We also observed that the times of descent for various inclinations of the plane bore to one another precisely that relation which, as we shall see later, the author had predicted and demonstrated for them "*

The law referred to in the last sentence is essentially that the velocity is given uniquely by the vertical drop. This Galileo proved in a most ingenious way by drawing aside the bob of a heavy pendulum until it reached a fixed height, and letting it fall so that the string struck a nail vertically under the point of support. No matter at what height this nail was placed, that is, no matter what the curvature of the arc along which the bob rose, the height which it attained was always the same, and equal to that through which it fell. The velocity at the lowest point being always the same, it follows, considering the motion reversed, that the velocity is independent of the curvature of the arc along which the bob is constrained to move. From this he concluded that a similar result would hold true for planes of different slopes.

The parabolic law for projectiles Galileo proved by combining a uniform velocity in the horizontal direction with the law of fall, having previously proved that, with a body projected vertically upwards, the time of rise to the highest point is equal to the time of fall from that point. With great ingenuity he verified the parabolic form by rolling a metal ball on a slightly inclined plane metallic mirror "In the execution of this method, it is advisable to heat and moisten the ball slightly by rolling it in the hand in order that its trace upon the mirror may be more distinct " The experiment may be carried out to-day by covering with carbon copying paper a sheet of white paper attached to a board and rolling a heavy metal ball over it

It is hoped that these few words will be enough to suggest the acumen and experimental skill with which Galileo founded the science of particle dynamics. This work was the first great step towards the Newtonian synthesis, but of universal gravitation he had not the slightest inkling, as a passage where he speaks of dropping stones from the moon on to the earth is sufficient to show

BACON AND DESCARTES

In any account of the scientific thought of the seventeenth century there are two philosophers whose names always appear prominently, Francis Bacon and Descartes Bacon was a Lord Chancellor and Descartes was a great mathematician, but what we have here to consider are their writings on method, especially scientific method. As regards Bacon's services to science, we have a great diversity of opinion among those who have made a careful study of his works Macaulay, Spedding, and very recently, Prof R F Jones of the University of Washington, speak of him in terms of the highest commendation. On the other hand, William Harvey, the discoverer of the circulation of the blood , Liebig, the great chemist ; the philosophers Lasson and Duhring , the Anglo-American man of science J W Draper, who carried out important researches in photo-chemistry and was the author of the "History of the Intellectual Development of Europe" , and Sir Oliver Lodge, all speak strongly against his claims to be considered an important influence in the history of science.

Macaulay says of Bacon, for example, "As we have lying before us that incomparable volume, the noblest and most useful of all the works of the human reason, the Novum Organum . . .", which passage we may, perhaps, characterize in Macaulay's own words as the "noxious sweetness of his undiscerning praise". On the other hand, Aubrey tells us of Harvey that "he had been physician to the Lord Chancellor Bacon, whom he esteemed much for his wit and style, but would not allow him to be a great philosopher. . . .

---

* It need scarcely be said, perhaps, that the author referred to in this quotation is himself.

He wrote philosophy like a Lord Chancellor he said to me speaking in derision Draper is violent in his condemnation saying of Bacon that he was a pretender in science a time serving politician an insidious lawyer a corrupt judge a treacherous friend a bad man but he is no more violent than Liebig Elsewhere Draper says with justice that Bacon s chief admirers have been persons of a literary turn who have an idea that scientific discoveries are accomplished by a mechanico mental operation Finally we may quote Sir Oliver Lodge the kindliest and most courteous of men whose verdict is that on the solid progress of science he may be said to have had little or no effect

Bacon had a purely utilitarian view of science saying that the real and legitimate good of the sciences is the endowment of human life with new inventions and order To him is often attributed the adoption of the experimental method as distinguished from the speculative method of Aristotle and he himself is continually boasting that he brings a new method to the overthrow of Aristotle but his whole terminology is scholastic with its sensible qualities matter and form and he totally lacks any feeling for the methods by which science has been advanced He was a stranger to quantitative work and he had an aversion from the method of the working hypothesis to which science actually owes its advances One instance of this is his condemnation of the Copernican system which he holds to be the speculations of one who cares not what fictions he introduces into nature provided his calculations answer

It is characteristic of Bacon that while continually laying stress on his own work as a forerunner and of his importance as *instaurator artium* he totally ignores the pioneering scientific work of his great contemporaries He says nothing of Galileo although it is quite clear from a letter of Sir Tobie Matthew s which we possess that the work had been brought to his notice He derides Gilbert and when he himself discusses the magnet he ignores the repulsion between like poles Kepler and Harvey made no impression upon him although as we have seen he was in close personal touch with the latter In short he could not recognize real scientific advances when he saw them

In spite of Bacon s attack on Aristotle his outlook was really Aristotelian He says for example that we must investigate what bodies are light what heavy and what neither light nor heavy His whole treatment of motion is spun from his own mind in the Aristotelian tradition He lays down for example in the Novum Organum that there are nineteen different kinds of motion which he describes at length in the spirit of the Middle Ages rather than that of science as we understand it Of the last kind of motion for example he says let the nineteenth and last motion i e one which can scarcely be termed a motion and yet is one and which we may call the motion of *repose* or of abhorrence of motion It is by this motion that the earth stands by its own weight It is owing to the same tendency that all bodies of considerable density abhor motion and their only tendency is not to move which nature they preserve although excited and urged in a variety of ways to motion

For a general description of Bacon s method we will so as to avoid any appearance of prejudice adopt that of his worshipper Macaulay Make as large a list as possible of those bodies in which however widely they differ from each other in appearance we perceive heat and as large a list as possible of those which while they bear a general resemblance to hot bodies are nevertheless not hot Observe the different degrees of heat in different hot bodies and then if there be something which is found in all hot bodies and of which the increase or diminution is always accompanied by an increase or diminution of heat we may hope that we have really discovered the object of our search We will only add that among the hot bodies which he classifies are horse dung and pepper

The collection of the material Bacon was prepared to delegate to any journeyman The man of science was then to go through this material in a mechanical way according to the prescribed rules and so make great discoveries I hold that we can without unfairness say that he worked out elaborate and impossible schemes for investigating phenomena of no importance On the other hand it is indisputable that he was often cited with admiration by some of the great experimenters who founded the Royal Society and held up as the man who fought for the experimental method He appears for example in the frontispiece designed by John Evelyn and etched by Wenceslas Hollar for Spratt s History of the Royal Society which published in 1667 is really a history of the foundation and objects of the Royal Society Robert Boyle in particular always speaks of him with the highest praise even though he points out that Bacon's determination of the specific gravity of quicksilver is somewhat incorrect. "Whereby it appears the weight of water to quicksilver is as 1 : 13½⅝ though our illustrious Verulam (questionless not for want of judgement or care, but of exact instruments) makes the proportion between these two liquors to be greater than 1 : 17."

Newton, however, never refers to Bacon and Hooke certainly very seldom. I believe that the respect that some working men of science in the seventeenth century felt for him was due to his lofty position as Lord Chancellor and to the fact that he, influential and exalted as he was, spoke so strongly of the need for the experimental method and attacked Aristotle. That Bacon had no conception of the right way of applying the experimental method and himself used the terminology and almost the method of Aristotle is unimportant compared with the fact that he continually spoke of the need for a new method which should handle observed properties. Again, in the "New Atlantis" Bacon describes Solomon's House "dedicated to the study of the Works and Creatures of God", which was his scheme of a great institution for experimental research. A foundation of this kind was the dream of the men who did most to found the Royal Society, and Bacon's fiction of a munificently endowed college for scientific research was one that set him high in the esteem of the enthusiasts of the new learning.

Renée Descartes offered a mechanical explanation of the universe evolved by him from a philosophical theory of first causes. His system had a far-reaching influence. Its ready acceptance was no doubt due to the way in which he explained all phenomena in general and pictorial terms which could be followed without any mathematical discipline, for great as were Descartes's mathematical powers his mechanism of the universe was purely quantitative. In spite of the overthrow of the system by Newton in 1687 his influence continued far beyond the end of the seventeenth century, especially in France, where great controversies between Cartesians and Newtonians took place round about 1735.

Descartes set out in the Aristotelian spirit to build up his scheme from first causes, and he criticizes Galileo for ignoring such causes, saying that by doing so he had built without foundation. Descartes assumed extension as the essential property of matter; as there could be no extension without matter there could be no vacuum. Motion of matter was only possible if something material occupied the space vacated by the moving body. It was from arguments of this kind that Descartes evolved his vortices, in which matter moved in closed paths. He distinguished three kinds of matter. The original kind called into being by the Creator consisted of medium-sized particles which, from his fundamental ideas, cannot have been spherical but must have filled

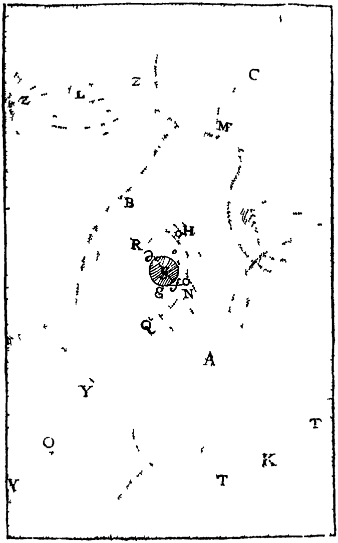

Fig. 3

DESCARTES'S SCHEME OF VORTICES, SHOWING THE VORTEX OF THE SOLAR SYSTEM IN THE MIDDLE.

all space without interstices These particles, when rubbed down by their continual motion, constituted his second kind of particles, or heavenly matter The dust rubbed off from them constituted the first kind of matter Some of these particles forced through the interstices of the particles of the second kind became spiral and matted together to form the third kind of particles The luminous sun and stars were formed of the first kind of matter, the heavens of the second and the crust of the earth and planets were formed of the third kind of particle

The heavenly vortices (Fig 3) themselves consisted of circulations of particles of the second kind, carried round by the rotation of the central bodies The planets were carried round by the sun's vortex Descartes develops his system in great detail, making it account for the formation of the earth, with its mountains due to the movements of the crust (Fig 4), for the phenomena of light and magnetism, in which latter connexion he was the first to show magnetic lines of force by means of iron filings, and for the motion of the heavenly bodies, including the comets, although the latter gave him particular difficulty The whole of his heavenly mechanics is purely descriptive he gives the particles of his vortices any velocities and properties that he likes, and he makes no attempt, for example to express quantitative laws, such as Kepler's laws, in terms of his fundamental conceptions

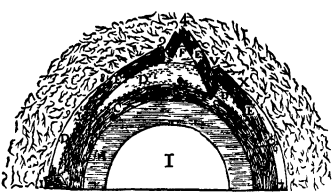

Fig 4

DESCARTES S SCHEME OF THE EARTH SHOWING THE FORMATION OF MOUNTAINS

Nevertheless, Descartes does lay down laws of motion, which foreshadow Newton's laws His first law is practically the law of inertia—every body, so far as it can, will persist in its particular state, so that what is once in movement will always be in movement The second law is that every body tends to move in a straight line and that bodies which move in a circle always tend to move away from the centre of the circle The third law dealt with impact

THE ROYAL SOCIETY AND ROBERT HOOKE

Although he dealt with the laws of impact, and with the laws of optics, Descartes laid no emphasis on experiment He did, however, attempt a general synthesis, explaining heavenly and terrestrial mechanics in terms of the same conceptions, and so made a great advance Descartes's life ran from 1596 to 1650 Somewhere towards the end of it (the exact time is not known) Guericke carried out his great experiment on the formation of a vacuum but Guericke's book De Vacuo Spatio' was not published until 1672

In the meantime Copernican views were gaining strength In 1638 for example, John Wilkins published a stout defence of the Copernican system John Wilkins is a figure of great importance for English science although he carried out no original work for he was instrumental in the formation of the Royal Society, the foundation of which, with the other great European academies, the Académie Royale des Sciences and the Accademia del Cimento, gave an immense impulse to the experimental method

It was in 1645 that Wilkins began to have in his rooms those gatherings of natural philosophers which formed the beginnings of the Royal Society We have not leisure to trace the history of these meetings nor the relative parts played by Oxford and London Suffice it to say that the Royal Society was founded in 1662, with Wilkins as the first secretary, and numbered among its original members Seth Ward, Robert Boyle Sir William Petty, Lord Brouncker Robert Hooke, John Wallis, Francis Willughby and Sir Christopher Wren, as well as Christian Huygens

The foundation of the Royal Society was followed by a burst of scientific discovery, in which Robert Hooke played a great part Robert Hooke, physically insignificant, crooked and weakly, was one of the greatest mechanical geniuses that the world has seen Pepys wrote of him "who is the most, and promises the least, of any man in the world that ever I saw" He lacked Newton's gigantic mathematical powers and searching analysis, but he had a wonderful instinct for scientific truth, and an extraordinary fertility of invention One or two quotations from his Attempt to prove the motion of the earth published in 1674 may give a taste of his quality In this treatise he describes among other things a very careful attempt which he made to measure the parallax due to the earth s motion with reference to the fixed stars and he correctly attributes his negative result to the distances of these stars saying

> To me indeed the Universe seems to be vastly bigger then tis hitherto asserted by any Writer when I consider the many differing magnitudes of the fixt Stars and the continual increase of their number according as they are looked after with better and longer Telescopes And could we certainly determine and measure their Diameters and distinguish what part of their appearing magnitude were to be attributed to their bulk and what to their brightness I am apt to believe we should make another distribution of their magnitudes then what is already made by *Ptolomy Ticho Kepler Bayer Clavius Grienbergerus Piff Hevelius* and others

At the end of the treatise Hooke quotes three suppositions upon which he says the system of the world should be founded

> First That all Cœlestial Bodies whatsoever have an attraction or gravitating power towards their own Centers whereby they attract not only their own parts and keep them from flying from them as we may observe the Earth to do but that they do also attract all the other Cœlestial Bodies that are within the sphere of their activity
>
> The second supposition is this That all bodies whatsoever that are put into a direct and simple motion will so continue to move forward in a streight line till they are by some other effectual powers deflected and bent into a Motion describing a Circle Ellipsis or some other compounded Curve Line The third supposition is That their attractive powers are so much the more powerful in operating by how much the nearer the body wrought upon is to their own Centers Now what these several degrees are I have not yet experimentally verified but it is a notion which if fully prosecuted as it ought to be will mightily assist the Astronomer to reduce all the Cœlestial Motions to a certain rule which I doubt will never be done true without it

Before saying anything further about the part that Hooke played as a forerunner of Newton we will briefly refer to some of his performances in other fields He was the first man to make a really successful compound microscope and with it made numerous discoveries including that of cells in plants which he was the first to name In connexion with his work on springs he enunciated Hooke's law, and he discovered the balance wheel of watches which probably Huygens discovered independently—the matter is disputed He invented a group of meteorological instruments—a hygrometer an anemometer a self registering thermometer and a self registering rain gauge In astronomy he devised the first clock driven telescope (Fig 5) and the first circle dividing machine which Ramsden afterwards perfected and he insisted upon the importance of telescopic sights in this connexion explaining and measuring the resolving power of the eye He was the first to carry out systematic experiments on the colours of thin plates and he invented an early form of Savart s wheel to be used as a siren His geological work especially that on fossils is fundamental Many other instances could be given of his fertile genius

Returning to the laws of celestial motion in 1679 Hooke who was then secretary of the Royal Society wrote to Newton to ask him for a paper to be read before the Society Newton replied with a letter concerning the place where a falling body would hit the surface of the earth pointing out that owing to the motion of the earth it would fall east of the perpendicular He also stated that the path should be a portion of a spiral terminating at the centre of the earth Commenting on this letter Hooke said that Newton was in error the path would be an eccentrical elliptoid supposing no resistance of the medium but supposing a resistance it would be an eccentric ellipti spiral the fall of the body would not be perfectly east as Mr Newton supposed but to the south east and more to the south than the east What Hooke meant by an eccentrical elliptoid we can only conjecture Probably he meant a curve something like an ellipse with the attracting point away from the centre his extraordinary physical instinct may well have been sufficient to assure him of this without his being able to prove that it was an ellipse Hooke s criticisms were substantially correct as Newton realized and to be caught in error irritated Newton in the highest degree In his reply Newton admitted that the body would fall to the south and that if gravity be supposed uniform it will not descend in the spiral to the very centre but circulate with an alternating ascent and descent made by its *vis centrifuga* and gravity alternately overbalancing one another

It is clear from this and the rest of the reply that Newton had not yet attained his later clarity on the problem of gravitation There is little doubt that this correspondence revived his interest in the problem, which, as we shall see, had been very keen some thirteen years earlier The bitterness between Newton and Hooke, which continued until Hooke's death, was a sad feature of the lives of two great men, both wholeheartedly devoted to scientific truth It seems certain that by the intercession of tactful friends it might have been much diminished, if not entirely removed Unfortunately, it was exacerbated by Oldenburg, long the secretary of the Royal Society, who missed no opportunity of embittering the relationship

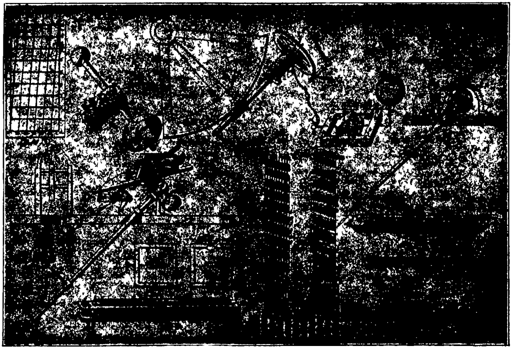

Fig 5

An engraving from Hooke's "Animadversions", showing Hooke's joint, the clock-driven telescope, the method of diagonal divisions, stepped and helical gears and the bubble level The last named is claimed for Thevenot, but there seems no doubt that Hooke invented it independently

Isaac Newton: Laws and Hypotheses

There is general agreement that Newton is the greatest scientific mind that the world has known. He produced that body of mechanics, founded on a few precise laws—the three laws of motion and the inverse square law of gravitation—which, in its essence, is still sufficient to cover the whole body of celestial and terrestrial mechanics of macroscopic bodies moving with velocities small compared with that of light He founded the science of mathematical physics, and was, in addition, an experimenter of the very highest order, as his "Opticks" and, for example, his experiments with pendulums suffice to show He also stated with the greatest clarity the attitude which has dominated physics from his time until the present day, with possibly one or two very recent exceptions This attitude we cannot express better than in his own words,

> "Hitherto I have not been able to discover the cause of those properties of gravity from phenomena, and I frame no hypotheses, *hypotheses non fingo*, for whatever is not deduced from the phenomena is to be called an hypothesis, and hypotheses, whether metaphysical or physical, whether of occult qualities or mechanical, have no place in experimental philosophy. In this philosophy particular propositions are inferred from the phenomena, and afterwards rendered general by induction Thus it was that the impenetrability, the mobility, and the impulsive force of bodies, and the laws of motion and of gravitation, were discovered To us it is enough that gravity does really exist, and act according to the laws which we have explained, and abundantly serves to account for all the motions of the celestial bodies, and of our sea "

His attitude here expressed is in direct contradiction to that of Descartes, who made hypotheses as a result of pure reflection and from these hypotheses constructed the world.

The history of Newton's theory of gravity begins at Woolsthorpe, where he was in 1665–66 to avoid the plague His own account of this period was written in 1714, and his recollections may have been coloured by what had happened in the intervening period, but his words are of such interest that I cannot refrain from giving them .

> "In the same year (1666) I began to think of gravity extending to the orb of the moon, and having found out how to estimate the force with which a globe revolving within a sphere presses the surface of the sphere, from Kepler's Rule of the periodical times of the planets being in a sesquialterate proportion of their distances from the centres of their orbs I deduced that the forces which keep the planets in their orbs must [be] reciprocally as the squares of their distances from the centres about which they revolve and thereby compared the force requisite to keep the moon in her orb with the force of gravity at the surface of the earth, and found them answer pretty nearly All this was in the two plague years of 1665 and 1666, for in those days I was in the prime of my age for invention, and minded mathematics and philosophy more than at any time since "

The extraordinary thing is that, at the time, Newton published nothing on the subject—extraordinary, perhaps, but less extraordinary with Newton than with any other man, because he always had to be urged to publication, largely, I think, because of his horror of controversy The generally accepted story is that, owing to a discrepancy of some 16 per cent, due to his taking an incorrect radius of the earth then current, Newton put the work aside, being dissatisfied with this degree of accuracy This does not, however, seem likely nobody better than Newton could estimate what degree of precision was likely to have been attained in a given measurement We must remember the hypotheses on which the calculation is based, namely, that the gravitational effect of the earth extends to the moon, falling off inversely as the square of the distance, and that the gravitational acceleration at the surface of the earth is only another manifestation of the earth's attraction. It is clear that when we are considering the moon it does not much matter at what particular point of the earth we consider the earth's mass to be concentrated, but when we are considering the surface acceleration this point is of the greatest importance. It is far from being obvious that the gravitational force at the surface of a sphere, each small part of which is exerting a force proportional to its mass and inversely proportional to the square of the distance, is the same as it would be if the whole of the mass of the sphere were concentrated at its centre Until this has been proved the whole calculation is unsatisfactory, especially to a mind so acute and so scientifically honest as that of Newton He would see at once that criticism could fasten on this point, and it seems far more likely that he put aside the work on account of his inability to answer such criticism than on account of the discrepancy to which his silence is usually attributed

By 1685 Newton had succeeded in proving that the gravitational attraction of a spherical shell of uniform density on an external point is the same as it would be if the mass were concentrated at the centre There was another point of difficulty it was by no means clear *a priori* that the gravitational attraction was proportional to the motional inertia of a body, or that the ratio of the two was the same for all bodies This point Newton settled by his famous experiments of the hollow pendulum carried out with enclosures of equal masses of very different substances—metals, glass, sand, salt, wood, wheat

The incident of 1679, to which we have referred, brought Newton back to the problem of the orbit of a particle in a central gravitational field In January 1683/4, Edmond Halley had a talk with Christopher Wren and Hooke on this problem All three, apparently, tended towards the belief that celestial mechanics could be explained on the inverse square law of attraction, and Hooke declared that he was able to demonstrate this mathematically Wren said that he would give a prize of "a book of 40s " to either of the others who could, in fact, bring a convincing demonstration It is quite clear that Hooke never did so, and equally clear that he was incapable of such a mathematical feat In August 1684, Halley, being at Cambridge, asked Newton what would be the curve described by a planet in an inverse square field of force and Newton immediately answered, "An ellipse", and, in reply to an amazed inquiry, said that he had calculated it Later he produced the proof

There is no space here to discuss how Halley instigated Newton to write the "Principia", saw the work through the press, and, although not a rich man, bore the charges It is pleasant to reflect that he probably got his money back, as the work sold very quickly. As a minor historical mystery there seems no certainty at what price it was sold. More says probably for ten or twelve shillings a copy.

The spirit of the Principia may be said to be summarized in the first sentence of the Opticks

My design in this Book is not to explain the Properties of Light by Hypotheses but to propose and prove them by Reason and Experiments The book is astonishingly rich in matter fundamental to mathematical physics containing for example the foundations of the theory of sound and of hydrodynamics The treatment of Descartes s theory of vortices is typical Newton points out that it is impossible on Descartes s theory to give a quantitative explanation of celestial mechanics in particular to deduce Kepler s laws In order to drag the planets round the fluid matter of the vortices must behave in a viscous manner Newton does not actually use the phrase viscous liquid but he lays down the fundamental behaviour of such liquids in the following hypothesis the resistance arising from the want of lubricity in the paths of a fluid is other things being equal proportional to the velocity with which the parts are separated from one another that is the shear in a viscous fluid is proportional to the velocity gradient From this he deduces that the periodic times of the paths of a fluid surrounding a revolving sphere are proportional to the squares of the distances from the centre of the sphere He further points out fundamental difficulties in the vortex hypothesis in connexion with the motions at perihelion He does not discuss the adequacy of the vortex hypothesis in general terms but demonstrates clearly that the hypothesis could not account for the observed laws of planetary motion The situation reminds us of the fate of the nineteenth century ether of space which gave the same kind of easily grasped picture as did the vortices but which had to be abandoned because it would not give the quantitative results required by the Michelson Morley experiment

Newton s attitude towards the question of the nature of gravitational force is typical of the man Richard Bentley pressed him strongly to declare himself on this point and we possess the letters which passed on both sides Two passages may be cited as of particular interest incidentally in the Royal Institution copy of Horsley s Newton these passages are marked in pencil and in each case we have the note at the side in Dr Bence Jones s handwriting Mr Faraday s marks Newton says

> You sometimes speak of gravity as essential and inherent to matter Pray do not ascribe that notion to me for the cause of gravity is what I do not pretend to know and therefore would take some time to consider it and again It is inconceivable that inanimate brute matter should without the mediation of something else which is not material operate upon and affect other matter without mutual contact as it must do if gravitation in the sense of *Epicurus* be essential and inherent in it And this is one reason why I desired you would not ascribe innate gravity to me That gravity should be innate inherent and essential to matter so that one body may act upon another at a distance through a *vacuum* without the meditation of any thing else by and through which their action and force may be conveyed from one to another is to me so great an absurdity that I believe no man who has in philosophical matters a competent faculty of thinking can ever fall into it Gravity must be caused by an agent acting constantly according to certain laws but whether this agent be material or immaterial I have left to the consideration of my readers

This completes the particular story which I have tried to tell What Newton ignores is what Aristotle and Descartes tried to start with

I have endeavoured to show how within a century the method of constructing Nature by reasoning more or less logically from accepted philosophical ideas was replaced by the method of appealing to Nature by experiment and adopting only such laws as were in quantitative agreement with the results of experiment I have tried to point out how the search in the mind for first causes gave way to a search in Nature for observable order and regularity coupled with a disinclination to speculate beyond the facts In a recent Friday Evening Discourse at the Royal Institution Prof Dingle spoke of a return to the Aristotelian method which he detected and deprecated in the writings of one or two of our great contemporaries in science What s to come is still unsure—it may be that a new spirit in science is being born just as it may be that future ages will envy us for having been contemporary with the creation of Mr T S Eliot s austere poems and Mr Epstein s mighty monoliths Be the future however what it may it is the spirit of Newton that has guided us hitherto and that is the legitimate father of the work of a Faraday a Rutherford and a Bragg

PRINTED IN GREAT BRITAIN BY FISHER KNIGHT AND CO LTD ST ALBANS

sponte circa Gissam nascentium which gained for him a considerable reputation The knowledge he showed of cryptogams induced William Sherard to persuade him to come to England mainly to help with the 'Pinex" he had undertaken on Tournefort's advice When Sherard died he left an endowment to found a chair of botany at Oxford stipulating that Dillenius should be its first occupant The drawings now received cover the whole period of Dillenius's activities, and include a set of copies from published works apparently made in his student days, the coloured figures of the fungi described in the Giessen catalogue, drawings of garden plants from Giessen, those in the third edition of Ray's Synopsis (which Dillenius edited) and many prepared and not used plants found on a Welsh tour in 1726, about 200 of plants growing in the Oxford Botanic Garden, 1744–46, Junci and Gramina Most of the material which Vines and Druce mention in 'The Dillenian Herbarium (1907) as having passed into the hands of Prof Humphrey Sibthorp and eventually disappearing and being no doubt irrevocably lost' has thus come to light The drawings show that Dillenius ranks much higher as a botanical artist than was generally thought It would be highly satisfactory if the numerous letters received by Dillenius from botanical correspondents could be similarly retrieved

Astrophysical Monographs

A VALUABLE new series of monographs on astrophysical subjects is being planned by the University of Chicago Press under the auspices of the *Astrophysical Journal*, the editorial board of this journal serving in a similar capacity for the new series Each monograph aims at being an exhaustive, comprehensive summary of a limited field written by an authority on the subject, and the whole should form a growing library of great use to astronomers and advanced students In the first monograph ("The Distribution of the Stars in Space" Sup Roy 8vo Pp xvi+124 Chicago University of Chicago Press, London Cambridge University Press, 1937 11*s* 6*d* net), Prof B J Bok deals with stellar statistics and galactic structure, dividing his subject into three sections—the methods of analysis, the data of observation, and problems of galactic structure In the first section a fuller treatment of the earlier mathematical methods, especially those developed by Charlier and others, would have been welcomed by many if the space had been available, but the necessary condensation has not impaired either the general sequence or clarity of this very readable mathematical section It has had also the advantage of allowing more complete and critical accounts of modern numerical methods of analysis and their application to determining the distance and absorbing power of a dark nebula The second section gives a useful summary of the relevant data of observation, and indicates where the need for further observations arises, while the last section deals with general problems of galactic structure of a more or less controversial nature Although his own views are freely expressed, the author succeeds in giving an impartial and stimulating account of the subject, together with some tentative conclusions suggested as working hypotheses to encourage further observational studies

History of Chemistry

WE have received a pamphlet by Prof E Pietsch, editor in chief of *Gmelins Handbuch der anorganischen Chemie*, which is entitled Sinn und Aufgabe der Geschichte der Chemie This is published by Verlag Chemie, Berlin, price 1 mark Prof Pietsch shows in a very convincing way the great utility of a study of the history of chemistry in the education of young chemists He deals with the subject in its cultural aspects and makes clear how such a study can do much to remove the dangers of over specialization now threatening chemists in the enormous development of minute detail which is occurring in the science He also shows that a knowledge of past problems can lead to a great economy of time and effort, since in many cases large amounts of time and trouble have been expended on matters which have been fully dealt with before but forgotten A knowledge of the history of applied chemistry also has a distinct commercial value, examples of which are given The text includes a very brief but surprisingly complete sketch of the history of chemistry taken as a whole, with its great periods of development The pamphlet is characterized by a maturity and a philosophical outlook which recommend it to all thoughtful students of science, and to chemists in particular it should prove stimulating and suggestive

Midland Naturalists' Union

REPRESENTATIVES of natural history societies in the Midlands meeting in the rooms of the Birmingham Natural History and Philosophical Society on June 18 unanimously decided to form a Midland Naturalists Union, membership of which is open to natural history archæological and similar societies in the counties of Monmouth, Hereford, Worcester, Warwick Leicester Rutland, Nottingham and Lincoln It is intended to organize an annual congress, several field meetings and in larger towns, a number of lectures during the winter months A list of lecturers willing to visit societies, a panel of referees for specimens and information in the various groups of plants and animals and other branches of natural history and archæology and a system of lantern slide exchange among members, are also being organized It is felt that the Union will facilitate co operative work among the societies as well as bring workers into touch with others in their own branches of the subject Further information may be obtained from the honorary secretary, G Brian Hindle, 55 Newhall Street, Birmingham

"Dechema"

THE annual meeting of the "Dechema" held in Berlin at the end of April was attended by about 500 people, a testimony both to the interest attached to chemical engineering subjects and to the organizing energy of its director, Dr Bretschneider Three reports dealt with standardization, one having relation to technical terms, another to drawings and a third to corrosion from the point of view of rendering measurements of corrosion made in different laboratories comparable At the Rome Conference of Chemistry it was agreed that certain questions of chemical standardization should be discussed internationally A further subject was the possible methods of testing chemical apparatus, which is notably subject to rapid wearing, without destroying it as is usual in engineering practice with test pieces A second lecture on corrosion dealt with recent efforts to make metal vessels stand up to hydrochloric acid, this is one of the outstanding problems of the chemical industry

Dismissals of Scientists in Vienna

IN addition to the scientific workers named in the letter under this title in NATURE of June 18, p 1101, Miss Margaret Gardiner has received the following further list of dismissals University of Vienna Prof Emil Dittler, mineralogist, Prof Arnold Durig, physiologist, Prof Kasimir Graff, astronomer Prof Friedrich Kottler, physicist, Prof Karl Menger, mathematician, Prof Hans Leitmeier, mineralogist, Prof Hans Przibram zoologist, Technical High School Prof Alfons Klemenc, chemist, Prof Wolfgang Johannes Muller, chemist

Conference on Elasticity and Plasticity

A CONFERENCE on 'Elasticity and Plasticity will be held under the auspices of the Institute of Physics (Manchester and District Branch) in the Physics Department of the University of Manchester on July 4–5 On July 4 the opening lecture by Prof G I Taylor will take the form of a general theoretical survey, and will be followed by lectures on the elastic properties of metals by Dr R W Bailey, and on the plastic properties of single crystals by Prof E N da C Andrade On July 5, lectures will be given by Dr F T Peirce on the elastic properties of fibres, by Dr J B Speakman on the elastic properties of wool, and by Dr W G Wearmouth on the elastic and plastic properties of synthetic resins Each lecture will be followed by discussion Visitors will be welcome Further particulars may be obtained from the Honorary Secretary of the Branch, Dr W H Taylor, Physics Department, College of Technology, Manchester, 1

Royal Sanitary Institute

THE Health Congress of the Royal Sanitary Institute will be held at Portsmouth under the presidency of the Earl of Bessborough on July 11–16, when the following subjects among others will be discussed the future of the general hospital, the defects found in school entrants and the steps to be taken before entering school life, behaviour and nervous diseases in children, food manufacturers contributions to public health, the Food and Drugs Act 1937, meat and food inspection and air raid precautions The Health Exhibition arranged in connexion with the Congress will include foods, sanitary appliances, and exhibits illustrating municipal action and hygiene in the home Further information can be obtained from the Secretary of the Institute, 90 Buckingham Palace Road, London, S W 1.

Announcements

THE Committee of the Privy Council for the Organisation and Development of Agricultural Research has appointed the Earl of Radnor, lord warden of the Stanneries, chairman of the Lawes Agricultural Trust, and a member of the Council of the Royal Agricultural Society of England, and (after consultation with the president of the Royal Society) Sir Joseph Barcroft, emeritus professor of physiology in the University of Cambridge, and formerly Fullerian professor of physiology in the Royal Institution, to be members of the Agricultural Research Council in succession to Lord Richard Cavendish and Sir Frederick Gowland Hopkins Sir Thomas Middleton is succeeding Lord Richard Cavendish as chairman of the Council

PROF MAX PLANCK of Berlin, who is an honorary fellow of the Royal Society of Edinburgh was the guest at a dinner held in his honour in the rooms of the Society on June 23 The president, Sir D'Arcy Wentworth Thompson, was in the chair

DR W H GEORGE, lecturer in physics at University College, Southampton has been appointed head of the Department of Physics at Chelsea Polytechnic, in succession to Dr L Lownds, who is retiring after thirty seven years service

DR C E FORD, demonstrator in botany, King's College University of London has been appointed geneticist to the Government Rubber Research Scheme, Ceylon

COLONEL CECIL BIRT, late I A M S, who died on March 18, left estate of the gross value of about £35 000 He bequeathed all his property, subject to life interest to the Library Endowment Fund of the Royal Society of Medicine in appreciation of the services which the library renders to fellows

The Selborne Society has started a fund for a memorial to the late Lord Leigh, who, during the ten years that he was president of its section which arranges visits to people and places of interest, took an active part in the work of the Society Mrs E M Richardson Rice, who introduced Lord Leigh to the Selborne Society in the year 1926, has consented to receive contributions at 67 Eardley Crescent, Earl's Court, S W 5

PROF HEINRICH GINS, director of the Robert Koch Institute for Infectious Diseases of Berlin, has been elected an honorary member of the Bulgarian Postgraduate Institute of Veterinary Surgeons

AN international course in leprosy will be held on July 18–September 17 at the Institute of Malariology in Rome The lectures, which are intended for foreign medical men, will be delivered in French. Further information can be obtained from the director of the Institute, Prof G Bastianelli, Policlinico Umberto 1, Roma.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 40.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Optical and X-Ray Examination and Direct Measurement of Built-up Protein Films

Blodgett, Langmuir and co-workers[1] have described how piles of protein monolayers may be built up on a chromium plated metal slide by successive vertical movements of the latter through a monolayer spread on a liquid substrate. Following this technique, we have built up from recrystallized egg albumin at its isoelectric point films composed of up to 1,764 monolayers.

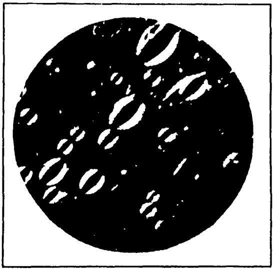
Our first apparatus was operated by hand, but a later design, which will be described in detail elsewhere, was automatic and enclosed, the film being dried for four minutes in a stream of nitrogen after each upward movement.

X-ray examination of even the thickest films *in situ* gave only disappointing results, because of the overwhelming effect of reflections from the metal slide itself; but fortunately it was found that the thicker films could be stripped off, and the way was at once opened up to a variety of experiments.

The first observation of significance was that the films tend to tear parallel to the direction in which the slide was moved through the liquid surface. The next was that, unlike built-up films of barium stearate for example[2], they are birefringent when viewed perpendicular to the surface, and the slow vibration is also parallel to the direction of movement of the slide. The most striking discovery, however, was that our first thicker films show numerous boat-shaped holes—presumably negative tactoids—again all pointing parallel to the direction of movement of the slide, and framed by regions of much higher birefringence still. The accompanying illustration is a photomicrograph between crossed nicols of a stripped film of 1,764 monolayers at 45° to the extinction position. The birefringence of the intact film approaches that of wool, while in the immediate neighbourhood of the holes it is at least as high as that of natural silk (0·05)*. This preliminary optical examination indicates also that the fastest vibration lies in the plane of the film, and the intermediate vibration lies perpendicular to the film.

The most perfect film, of 1,450 monolayers, was built up with the improved apparatus. Its optical properties were similar, but the boat-shaped holes were absent. In compensation, though, it offered a piece of evidence perhaps even more convincing than that of the tactoids—a fringe of delicate, but very real, fibres, once more parallel to the direction of movement!

By dint of repeated folding, stripped ribbons of film were formed into flat, correctly oriented, pads and photographed by X-rays. The photographs correspond to polypeptide chains lying roughly parallel to the direction of movement of the slide, with their side-chains roughly perpendicular to the plane of the film. The dried films are obviously imperfect in the crystallographic sense, whatever they were at the moment of laying down; and they are not composed of 'globular' protein, in the sense of the original egg albumin molecule. The cohesive forces evoked by drying seem to have brought about aggregation at the expense of orientation, as one would rather expect, in view of the fact that the main chains, and still less the side chains, of successive monolayers will in general neither fit nor match. The simplest description of the X-ray photographs so far obtained is that they are analogous to those of keratin that has been squeezed laterally in steam[3]; this treatment not only brings about the α–β transformation, but also tends to orient the side chains perpendicular to the plane of flattening. Actually, some of the film photographs show more reflections than those of keratin, and there is a distinct hope that with better orientation of the main chains it may be found possible to determine the amino acid period.



Two further deductions deserve special emphasis. The first is that since the up and down movement of the slide through the monolayer on the substrate has resulted in the deposition of polypeptide chains roughly parallel to the direction of movement, we have here the familiar process of spinning long-chain molecules[4], *and the chains must pre-exist on the surface of the substrate*: there cannot be groups closed more tightly than can be opened and oriented by the movement of the slide. The second deduction is that since there is apparently no thickening of the film round the negative tactoids comparable with the great increase in birefringence, the latter must be due to more perfect parallelism of the chains , and since the enhanced birefringence agrees with that of oriented polypeptide chains almost devoid of all but the shortest side chains, namely, those of natural silk, we have a peculiarly satisfying demonstration, quite apart from the X ray evidence that the side chains do indeed tend to lie perpendicular to the plane of the film, as had already been inferred from monolayer studies[5] and from independent X ray data[6]

Finally, we have succeeded in measuring the thickness per monolayer by direct mechanical means Our first method was to insert the film under one of the feet of a small three legged interferometer*, thus altering the angle of an air wedge included between two pieces of optically flat glass, the upper piece being attached to a balanced metal frame supported by the three legs, and the lower forming the actual table on which rested the film and the three feet By this means—and it should be noticed that no optical properties of the film itself are invoked—we have measured the thickness of films composed of 600, 800, 1,000, 1,450 and 1 764 monolayers, respectively, and the results all agree in fixing the thickness per monolayer at about 9½ A , and not 20 A as was first suggested[7] The value 9½ A agrees well with the side chain spacing given not only by the films under discussion, but also by β proteins in general

The second method was by way of being a *tour de force*, but it was sufficiently accurate to point once again to a thickness per monolayer of about 10 A It consisted in measuring the thicknesses of various folded pads of film with a screw micrometer ! Need less to say, the thrill of being able for the first time to measure the thickness of a protein chain by such a means far outweighed the satisfaction derived from the more elegant methods

Œstrogenic Activity of Alkylated Stilbœstrols

In a previous communication[1] we described the œstrogenic activity of 4 4'-dihydroxy α β diethyl stilbene (diethylstilbœstrol) It was shown that this substance was fully œstrogenic in doses of 0 004 mgm given subcutaneously dissolved in oil, and 0 001 mgm. when given by mouth It is thus several times more potent than œstrone and at least as potent as œstradiol The following communication is concerned with the activity of a series of compounds in which substituents other than the ethyl group are attached to the α and β carbon atoms The method of testing was on ovariectomized rats by the usual technique

Table 1 indicates the results in this series of compounds and gives the potency of the substances in relationship to œstrone In view of the fact that maximum activity is represented by diethylstilbœstrol, a number of esters of this substance have been prepared and are being tested

In Table 2 will be found the activity of a series of derivatives of dihydroxydiphenylbutadienes Here again the maximum activity is present in 4 4' dihydroxy γ δ diphenyl β δ hexadiene This substance appears to possess an activity equal to that of diethylstilbœstrol The correspondence in the effects of substituents in the two series is noteworthy and the large effects of relatively small changes may be thought to support our view that the middle section of the molecule conforms to the œstrone pattern when the substituents are ethyl or ethylidene groups

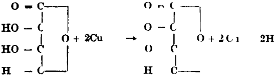
Polarographic Estimation of Vitamin C

AQUEOUS solutions of vitamin C, when electrolysed at the dropping mercury cathode, do not produce any effect on the current voltage curves. If, however, to a solution of vitamin C—freed from air—a mild oxidizing agent, such as cupric chloride, silver nitrate, gold chloride, ferric chloride or iodine is added, a polarographic wave appears on the current voltage curve at − 1·60 v. (from the calomel zero). This wave has been shown to be due to the deposition of free hydrions liberated in the solution by the reaction

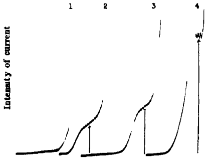


ascorbic acid

dehydroascorbic acid (anhydrous form)

This polarographic effect is not specific for vitamin C, as it may be also caused by the presence of other oxidizable compounds like glutathione or cysteine. It is remarkable that the oxidized form of vitamin C, namely, the dehydroascorbic acid, is not electro-reducible at the dropping mercury cathode. It probably changes irreversibly into a hydrated form.

However, a characteristic polarographic effect of vitamin C is obtained when the dropping mercury electrode is polarized as anode. Then a polarographic wave appears at about + 0·3 v. from the potential of a reversible hydrogen electrode and is shifted according to the pH of the solution. For practical purposes it is best to keep the solution at pH 7 in an $N/15$ phosphate buffer solution, in which the anodic effect of chloride ions or of glutathione does not interfere with the position of the polarographic wave of ascorbic acid (see the accompanying graph).



ANODIC WAVES DUE TO VITAMIN C.
CURVE 1: PURE $N/15$ PHOSPHATE BUFFER pH 7. CURVES 2 and 3: 0·5 AND 1·0 C.C. ORANGE JUICE ADDED TO 4 C.C. BUFFER SOLUTION. CURVE 4: 0·5 C.C. OF 0·01 M ASCORBIC ACID ADDED TO 4 C.C. BUFFER SOLUTION.
SENSITIVITY OF THE GALVANOMETER 10^{-7} AMP./MM. 1 CM. OF ABSCISSA = 0·2 VOLT.

We have ascertained that vitamin C may be estimated with the usual polarographic sensitivity and accuracy, like hydroquinone[1], that is, down to concentrations of 10^{-5} molar, which means 1 γ of vitamin C in the 1 c.c. necessary to carry out the analysis.

As vitamin C is polarographically active only in the reduced form, the analysis should be carried out in absence of air. For that purpose 0·5–1 c.c. of the fresh lemon or orange juice is added to 4 c.c. of the phosphate buffer (pH 7) freed from atmospheric oxygen. If the polarographic curve is recorded shortly after mixing, good results are obtained even in the presence of air.

Extractions from animal tissues, however, offer difficulties, inasmuch as other constituents seem to hinder the electrode reaction.

Full details of this investigation will be published elsewhere.

Biological Assay of Vitamin E

THE recent communication from Karrer *et al.*[1] makes it inevitable that comparisons will soon be needed between the biological activities of various substances having the properties of the anti-sterility vitamin. In particular, interest is likely to centre round the relative potencies of the various tocopherols and of synthetic substances. The preparation in these laboratories of a curve relating dosage and response to vitamin E[2] has enabled us to interpret the results obtained with specimens of highly purified tocopherol allophanates, and so to contribute some evidence as to the relative activities of the α- and β-forms, a matter on which the literature contains rather indefinite reports.

In accordance with our practice, we have compared the mean fertility doses of the substances—that is, the doses that will cause 50 per cent of implanted animals to bear live litters. During the test all conditions are kept as uniform as possible, virgin animals only being used and the doses being divided into ten equal portions and administered every day for the ten days following positive mating. The table below summarizes the results so obtained; the figures for the mean fertility doses refer to weights of tocopherol calculated from the weights of the allophanates which were carefully hydrolysed and dissolved in cod liver oil for feeding to the test animals.

Substance	M.P.	No. of animals used	Mean fertility dose
α-tocopherol	160° C.	*9	1·2 mgm. (weighted)
β-tocopherol	142·3° C.	†6	1·9 mgm.

* At two different levels; a still higher dose gave 100 per cent fertility.
† At one dose level; tests at several lower doses gave almost complete sterility.

The specimens of tocopherol were both derived from wheat germ oil concentrates. The highly purified allophanates were prepared by Dr. A. R. Todd, for whose assistance we are very grateful, from crude allophanates supplied by Dr. B. K. Blount, of the Chemical Research Department in these laboratories.

Vitamin E Synthesis of α-Tocopherol

THE recent announcement by Karrer Fritzsche Ringier and Salomon[1] makes it desirable for us to place on record the fact that we have also synthesized racemic α tocopherol by a rather simpler method namely, direct condensation of phytol with ψ cumoquinol by heating a mixture of these two substances in presence of a little zinc chloride This synthesis like that of the Swiss workers while it confirms the view originally expressed by ourselves[2] and by Fernholz[3] that the tocopherols are chroman or coumaran derivatives nevertheless fails to distinguish between the two types of structure

Karrer s arguments[4] in favour of a coumaran structure for the synthetic product rest on an assumption that phytyl bromide will condense with a phenol in exactly the same way as allyl bromide This assumption seems to us unjustifiable and it is indeed more probable that condensations of this type would lead to chroman structures when phytol derivatives are used Recent degradative evidence although inconclusive is on the whole more indicative of a chroman structure for the tocopherols[3,5]

On the synthetic side we have found that 6 hydroxychromans 5 hydroxycoumarans and α and β tocopherol are nearly identical as regards absorption spectrum reducing properties and effect of esterification on absorption spectrum

We are at present engaged on the synthesis of the tocopherols by unequivocal methods since it seems that only in this way can a final decision be reached as to their structure

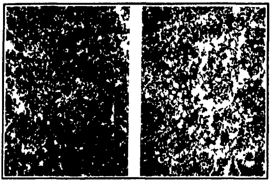
Formation of Hæmolymph Glands in Tumour-Bearing Rats

A CHANGE has been observed in the appearance of the lymph glands of rats bearing a Jensen sarcoma, the animals being examined usually fifteen to eighteen days after the subcutaneous inoculation of the tumour While the lymph glands of normal rats were found to be almost entirely of a light yellowish colour a more or less large number of the lymph glands of the tumour bearing rats showed, to a varying extent and degree a red discoloration The change occurred in glands of all regions although unequally and in an irregular manner in different animals The size of the tumour and the age of the animal, within the given limits, appeared to have little influence

Microscopical examination of these lymph glands showed that a conversion into more or less pronounced hæmolymph glands had taken place The normal lymph tissue had to a varying extent disappeared Its place was, in the first instance taken by red blood corpuscles, which were more or less densely aggregated Among them could be observed, in most cases, a considerable number of particularly large, sometimes pigmented cells, probably the descendants of normal (non lymphocytic) tissue cells The whole of this structural change is evident from a comparison of the accompanying illustrations In each is illustrated part of a section through a lymph gland taken from the left axilla of a female rat (*a*) referring to a normal animal (weight about 170 gm) and (*b*) to an animal bearing, at the right side a sarcoma of more than 50 gm weight (animal weight without tumour about 160 gm inoculation fifteen days before examination)



(*a*) (*b*)

STRUCTURE OF A LYMPH GLAND (*a*) FROM A NORMAL RAT (*b*) FROM A TUMOUR BEARING RAT HÆMATOXYLIN—EOSIN (× 120)

The simplest explanation of the origin of this change appears to be that it is due to the action of a certain substance produced by the growing tumour cell Investigations with the aim of finding out the chemical nature of this substance are now in progress In this connexion it is of interest to note that a similar change was previously observed in the lymph glands of rats which had received a series of subcutaneous injections of a preparation of carcinogenic tar[1] Further it is important that Clarkson Mayneord and Parsons[2] have obtained a corresponding result with the lymph glands of animals which had been irradiated with X rays In addition the authors mentioned that a derivative of 1 2 5 6 dibenzanthracene was likewise capable of producing the change

Kallikrein as a Reynals Factor

THE spreading or diffusing factors also termed Reynals factors or shortly *R* factors after F Duran Reynals[1], who found these factors in watery extracts of testicle of mammals are endowed with the property of enhancing tissue permeability When indicators, such as Indian ink, trypan blue or diphtheria toxin are added to such extracts and a certain amount of the mixture is injected intracutaneously in rabbits, an extensive spread of the particles of Indian ink trypan blue or the toxin takes place, resulting in much larger coloured or inflamed areas than can be obtained by mixing other substances (excluding the few other *R* factors) with the indicators As a control in experiments with *R* factors a mixture of 0 9 per cent sodium chloride with the indicator is generally used

Duran-Reynals has found the *R* factors in lesser amounts in several other organs D McClean[2] found the factors in certain anaerobic bacteria. E. Boyland and D. McClean[3] showed the existence in relatively great amounts of spreading factors in malignant transplantable tumours, in embryos and in placenta A. Claude[4] demonstrated the factors in leech extract, especially in extracts of the head of the leech

Recently, *R.* factors were found constantly present in human urine (J F. Christensen[5]) In a search for the substance responsible for the spreading effect of urine, an examination was made of Kallikrein, which was found in repeated experiments to be as active as, or even more active than, the *R* factor from testis in spreading properties An example will illustrate this : Solutions containing 30 mgm. of Kallikrein per c.c. and 3 mgm. Kallikrein per c c and solutions of the same concentrations of a purified testis extract were prepared To these solutions and to a control solution of 0·9 per cent sodium chloride were added equal amounts of diphtheria toxin diluted 1–1,000, 0·25 of each solution was injected intracutaneously in rabbits, in the shaved skin of the back.

With the Kallikrein solutions, the areas of inflammation produced were 47·8 cm ^{2} and 33·9 cm ^{2} respectively. With testis extract the areas obtained measured 29 6 cm ^{2} and 21·1 cm ^{2} respectively The control area . 5·6 cm ^{2} Measurements were made 24 hours after injection

Titrations to the end-point are being carried out A new method for standardizing Kallikrein seems possible

The identity of the various *R* factors has never been established and little is known of their chemistry. In all known respects—solubility, precipitability, sulphur reaction, diazo-reaction, non-diffusibility and nitrogen content—Kallikrein is in accordance with the testis factor. It seems as if testis extract (*R* factors) has not been examined for blood pressure lowering effect. As the preparation of *R* factors from testis by the methods used hitherto involves at least a contamination with activated Kallikrein from the blood content of the organ, a blood-pressure lowering effect of the *R.* factor preparations from testis may be expected

Details and further experiments will be published shortly.

Intense Radioactivity of the Superficial Ocean Floor

IN connexion with a recent discussion on the relation of the existing degree of terrestrial isostasy to the broken stratification that often accompanies it[1], a report of delicate investigations of core samples of some length taken from the mud of the deep ocean bottom (where there is excess of isostasy by stretching[2]) initiated and carried out for some years with great ingenuity by the Carnegie Geophysical Laboratory at Washington, D.C., thus exposing the course of recent geological history, and especially the excessive radioactivity (already somewhat in evidence) revealed in these superficial soft cores, is a development not to be overlooked[3].

The early results of the present Lord Rayleigh, Dr Joly, and others had shown that if the radium content of the surface rocks were to continue undiminished downward towards the centre of the earth the generation of heat arising from its degradation alone would be far in excess of the observed total output of terrestrial heat at the surface It has to be presumed, therefore, that when the earth's contents settled down originally into a planet, the deposition of uranium, the parent of radium, in the central parts was prohibited, by some agency which it is for the chemists to explore, so that it was gradually pushed up towards the surface The point now to be made is that this would be quite in keeping with Dr Piggot's ingenious and interesting theory, that it is to the chemical interactions endured by the uranium in the oceanic waters that the excessive deposit downward of uranium, and therefore of the more transient radium, which is found on the outer skin of the oceanic floor, must be traced[4] This additional indication towards the ways in which the various features of the geophysical landscape, such as stratigraphy, isostasy, radioactivity, can unexpectedly interlock must here suffice

[4] It is reported that investigation as to the total depth of the deposit is now in progress at Cambridge by E C Bullard

Micro-Organic Rock Weathering

THE following results obtained in 1922 by the late Sir John Harrison, formerly director of science and agriculture in British Guiana, may interest pedologists They represent the chemical composition of percolated water that had passed through sterilized granular masses of dolerite and of granite packed into four glass cylinders set up in the laboratory. In two experiments, the materials were inoculated with washings from the surfaces of weathering rock of the same kind , in the other two, the conditions throughout were sterile.

The comminuted rock, passing a 40 mesh to the inch sieve, but not a 100 mesh sieve, weighed about one kilogram in each experiment Sterilized water was added to each cylinder every other day on twenty-five occasions The volume of the collected drainings in each experiment was 1,600 c.c., the rate of percolation being adjusted to 13 c.c. per hour during the successive 5-hour periods of the treatment. The rock grains were thus intermittently covered with stationary water-films for a total period of 1,075 hours.

The chemical analyses were performed by Mr. G. C. L. Bourne, assistant chemist in the British Guiana Department of Agriculture ; thanks are due to him for abstracting the data from Sir John Harrison's posthumous records, and to Prof. J S. Dash, director of agriculture, for permission to publish them

The degree of hydrolytic weathering is greater (by 33 and 19 per cent respectively) for the inoculated rock materials ; the increases mainly concern calcium and magnesium among the basic radicals, and carbonate (or bicarbonate) among the acidic radicals. Ferrous iron seems to have been oxidized to ferric in the inoculated materials.

Analytical Results (expressed in parts per million)

Radical	Dolerite		Granite	
	Sterile	Inoculated	Sterile	Inoculated
K	11.6	14.6	16.9	14.1
Na	33.6	48.0	29.3	24.5
Ca	47.7	69.5	13.3	33.4
Mg	12.6	20.8	2.0	3.4
Fe (ous)	2.9	0.8	4.3	1.4
CO_3	64.6	134.8	63.7	93.0
SO_4	154.7	150.1	21.5	14.4
Cl	1.7	1.6	1.9	1.6
SiO_3	11.1	10.9	12.5	11.1
Salinity	339.5	451.1	165.4	196.9
per cent increase		3		19

That micro-organisms may be involved in rock weathering had previously been suggested by Sir Thomas Holland in his account of the origin of laterite in the humid tropics[1]; other authorities have more recently suggested that they might also be involved in the decay of building stones.

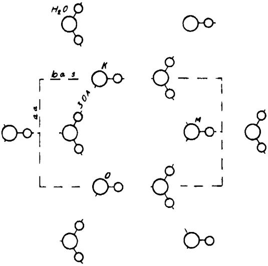
Crystal Structures of the Clay Mineral Hydrates

The manner in which water is adsorbed on clays has long been a matter for speculation. Structure determinations for the clay mineral hydrates throw new light on this question. These hydrates are the minerals vermiculite, hydrated halloysite and montmorillonite. Their compositions, subject to isomorphous replacements, are $(OH)_4Mg_6Si_8O_{20}.8H_2O$, $(OH)_8Al_4Si_4O_{10}.4H_2O$ and $(OH)_4Al_4Si_8O_{20}.nH_2O$ respectively. Each structure contains sheets formed by joining tetrahedra of oxygen atoms around silicon atoms into interlocked hexagonal groupings as first described by Pauling[1]. These are combined with octahedra of oxygen atoms and hydroxyl ions about magnesium and aluminium ions forming layers the compositions of which in a unit are given by the above formulæ.

It is now shown that such hydrates contain layers of water molecules as illustrated in the accompanying figure and that these are interleaved with the silicate structure. Their stability derives from the attraction between hydrogen atoms of one water molecule and oxygen atoms of other water molecules after the manner of hydroxyl binding as described by Bernal and Megaw[2]. Since each side of a hexagon corresponds to a single hydrogen atom, hydrogen atoms of half the water molecules, *K*, *M* and *O* of the figure, must be directed away from the net. These bind the water network to oxygen atoms in the top of the silicate layer, there being similarly placed oxygen atoms in that layer. In vermiculite there are two such sheets of water molecules between the silicate layers, the upper and lower surfaces of which are formed of oxygen atoms. Hydrated halloysite, on the other hand, has but a single sheet since hydroxyl groups form the bottom of the silicate layer[3].

Montmorillonite, the swelling clay, also probably forms hydrates of this type. Information in the literature is misleading in that it indicates (*a*) too great an amount of water and (*b*) a continuous change of (001) spacing with water content. In the first instance the total water is not a measure of the amount between the layers since it includes surface adsorption which is also of the sheet type. Continuous change of spacing does not mean a continuously varying separation of layers but can as well arise from random combination of a few definite values corresponding to 0, 1, 2, etc., sheets of water molecules per silicate layer.



This hexagonal network of water molecules is somewhat related to the hexagonal rings of hydroxyl groups in boric acid, H_3BO_3[4]. It more closely resembles the hexagonal ring of water molecules in $(CH_3CHNH)_3.3H_2O$, which is the hydrated polymer of acetaldehyde ammonia[5]. However, the clay mineral hydrates differ from this compound in that the oxygen atoms form an hexagonal network in which they are quite closely coplanar.

Model Experiments on the Minimization of Structural Vibrations caused by Seismic Disturbances

Even should the design of earthquake-resistant structures be based on stiff constructions resistant even under resonance against seismic vibrations of relatively low frequencies, it has not been possible as yet to average out the pronounced peaks in the seismic vibration curves of resonances; in the seismic vibration the amplitude is particularly large in the horizontal direction and the vibration of structures is most sensible for the horizontal movement of the foundations. Experiments have been made therefore on the horizontal movement of a model foundation table. After several experiments with different conditions of loading, it was found that vertical loads placed on a group of shot (ball or spheres of equal diameter) are very effective as a practical method of flattening the resonance curve, the load on the shot acts as a very good damper of the vibration, and is more effective the nearer to the roof it is placed.

Fig. 1 shows the free vibration curve of a frame structure (4 × 20 cm = 80 cm high, 20 cm. bay and 1 cm thick), the load conditions and period of which are indicated in the figure Fig 2 shows the same free vibration curve damped by an indirect load on ball-bearings, the load conditions of which are indicated in the figure These damping characteristics are the principal object of the studies described in the present note

Electrolytic Field Plotting Trough for Circularly Symmetric Systems

THE method of plotting electrostatic equipotentials between conductors by measuring the potentials in a geometrically similar problem in conduction is very old and well known. We have applied this to a modified form of electrolytic trough which we have been using in this laboratory for the past four years. This has been specially designed for circularly symmetric systems.

It is always permissible in problems of conduction to introduce along any surface an insulating barrier across which there is no flow of current. We have applied this to circularly symmetric systems by cutting the system along two diametrical planes, thus obtaining a liquid wedge. Such a wedge is realized in practice by a tilted trough containing electrolyte resting on a plane insulating bottom. If the angle of the wedge is small, the electrodes used in it need not be surfaces of revolution but can be replaced by pieces of metal sheet bent to the shape of a longitudinal section of the actual electrode

A trough of the type described gives very satisfactory results if a few minor precautions are taken. It is necessary to produce a contact angle between the liquid and insulating bottom which approximates to the angle of the wedge as nearly as possible This is obtained by allowing the liquid to wet the bottom of the trough only up to the axis. Then by reducing the angle of tilt the desired contact angle can be got. The scale of the system is made as large as possible so that it is unnecessary to plot the field in the neighbourhood of the axis where capillary rise on the probe would introduce serious error In addition to the above-mentioned precautions it is, of course, necessary to observe all the usual points in working with an A C electrolytic bridge

Free Field Calibration of Microphones

IN connexion with the contribution by Messrs King and Maguire to this subject in NATURE of June 4, p 1016, it may be of interest to refer to a very similar method of calibration which has been in use by the Research Branch of the Post Office Engineering Department since 1933

The 'probe tube' device to which I refer[1] is so constructed that reflections of sound in the tube are practically eliminated This means that the acoustical impedance presented by the open end of the tube is substantially non-reactive The open end can therefore be exposed at one of the closed ends of the resonant air column which is used for calibrating, without affecting the positions of the nodes and anti nodes in the stationary wave system set up in the air column. The air particle velocity is measured by a Rayleigh disk located at the centre of the air column at any frequency of resonance at which the length of the column is an odd multiple of half a wave-length, and the sound pressure at the end of the column, that is, at the open end of the probe tube, is thus known. Since the tube is small, the calibration is the same as a free field calibration

With an air column about seven feet in length, calibration can be effected at more than forty values of frequency, extending from 80 to more than 6,400 cycles per second, without any readjustment of either the length of the air column or the position of the probe tube.

The absence of resonance in the probe tube enables the device to be used for measuring sound pressures at a point, not only in an unobstructed sound field, but also at the surfaces of solid obstacles or near the openings of resonators, without appreciably altering the pattern of the sound field

Relativity and the Speed of Light

THE hypothesis that light always seems to have the same speed in spite of relative motion of source and observer can be tested directly by measuring the speed of light received from approaching and receding stars This measurement can be made with high accuracy and a very short light path by W C Anderson s development of the Kerr cell method[1] Anderson s apparatus can be used at the eyepiece of coudé or polar telescopes and might perhaps be adapted for mounting on equatorials

If light from a star in motion ± v relative to the earth has speed c the hypothesis will be proved but if the light has speed $c \pm v$ the hypothesis will be upset and the Michelson Morley result very simply explained Only actual measurement can decide and it is surprising that relativity enthusiasts have not asked for the experiment to be tried

Combined Ascorbic Acid in Plant Tissues

THE letter from Guha and Sen Gupta recently published in NATURE[1] prompts us to give very briefly the results of some of our own experiments The technique we have used is based on that described for urine[2] We find that in cauliflower juice (to quote one experiment) the total indophenol reducing substances amount to about 0 280 m mol per 100 ml Of this free ascorbic acid accounts for some 0 007 m mol dehydroascorbic acid for 0 110 m mol and combined ascorbic acid (liberated by acid hydrolysis) for 0 150 mol The non ascorbic acid reducing substances are almost entirely in the combined form (liberated by acid hydrolysis) and amount to only 0 012 m mol per 100 ml of juice The combined ascorbic acid is non dialysable and is incompletely precipitated when the proteins are removed by metaphosphoric acid

Points from Foregoing Letters

Dr W T Astbury Miss Florence Bell Prof F Gorter and Dr J van Ormondt have built up protein films composed of up to 1 764 monolayers of egg albumin and having observed that such films may be stripped from their metal base have examined them optically and by X rays and measured their thickness by direct mechanical means The thickness per monolayer is about 9½ A agreeing with the X ray patterns and previous indirect estimates and the structure is one of polypeptide chains lying roughly parallel to the direction of movement of the slide with the side chains roughly perpendicular to the surface They infer that polypeptide chains pre exist in the monolayer on the liquid substrate

A table showing the œstrogenic activity of several derivatives of stilbœstrol is submitted by Prof E C Dodds L Golberg W Lawson and Prof R Robinson One of these synthetic compounds 4 4 dihydroxy γ δ diphenyl β δ hexadiene has an activity several times that of the sex hormone œstrone and equal to that of diethylstilbœstrol a synthetic compound previously investigated

Vitamin C (ascorbic acid) produces a characteristic polarographic curve with a dropping mercury electrode polarized as anode The effect may be used according to E Kodíček and K Wenig for the estimation of small amounts (1 γ) of ascorbic acid in orange and lemon juice but not in extracts of animal tissues

Determination of the relative vitamin E activity of α and β tocopherol separated as allophanates from wheat germ oil is discussed by A L Bacharach The β form has a somewhat greater antisterility action

Dr F Bergel A Jacob Dr A R Todd and T S Work state that they have synthesized α tocopherol by a simpler method than that employed by Karrer and co workers namely, by the direct condensation of phytol with ψ cumoquinol The authors consider that the tocopherols have a chroman rather than a coumaran structure

In rats bearing a Jensen sarcoma Drs A and M Lasnitzki have found a conversion of normal lymph glands into more or less pronounced hæmolymph glands A similar change has been observed in animals which had received injections of carcinogenic tar

Kallikrein injected in the skin of rabbits together with extract of testis is found by Dr J F Christensen to increase the area of inflammation as compared with the effect of extract of testis alone This indicates that Kallikrein acts as a diffusing or Reynals factor that is one which increases the permeability of tissues

Sir Joseph Larmor directs attention to the greater radioactivity of the ocean floor a fact explained by Piggot as due to the precipitation of uranium parent of radium from the ocean water Rayleigh and Joly have calculated that the amount of radium at the surface of the earth must be greater than in the interior These facts Sir Joseph considers are connected with the problem of terrestrial isostasy

Results obtained by the late Sir John Harrison showing that water containing micro organisms attacks granulated rocks (granite and dolerite) more rapidly than ordinary water are submitted by Prof F Hardy

According to Dr S B Hendricks hydrates of the clay minerals contain layers formed by association of water molecules into hexagonal networks Adsorbed water on these and related layer minerals such as micas chlorites talc etc is also probably of this type

Prof F Takabeya finds that a load supported on balls or spheres of equal diameter and placed near the top of a frame structure is very effective in damping vibrations

The calibration of a probe tube device for measuring sound pressures in air is described by W West The tube is non resonant and can be used for measuring sound pressures near solid surfaces as well as in an unobstructed sound field

Research Items

Mesolithic Site at Piscop (Seine-et-Oise)

A MESOLITHIC site at Piscop (Seine-et-Oise) discovered by M. E. Giraud in 1930, has been excavated over a period of five years by MM. Giraud, C. Vaché and E. Vignard (*L'Anthropologie*, 48, 2–3; 1938). The site is situated on a slope of the Montmorency plateau. Stratification downward is as follows: (1) humus, 10–15 cm. thick, dark grey in colour, with a neolithic industry; (2) sandy soil, 20 cm.–1·8 m. thick, or more or less grey, with a mesolithic industry; (3) blackened indurated sand with a few objects of Upper Palæolithic date; (4) Fontainebleau sands of tertiary age, ochre yellow, sterile. In (1) no neolithic object was found at a depth greater than 15 cm. In the deposits of (2) the surface of the occupation level had been irregular. It also showed depressions and pits, the latter it was inferred from the contents being the remains of semi-subterranean dwellings. Smaller excavations may have been burials, though no bones, but only a considerable number of flakes and implements, were found in them. Four hearths were located and quantities of well-preserved charcoal, in which were implements of flint showing the action of fire. In all, 2,909 implements were found, of which 1,193 are classified as micro-burins, 422 as Tardenoisian 'pointes', 206 as triangular or scalene, and 243 as segments of a circle. Occupation of the site extended over a considerable period of time. Two phases are to be observed—an earlier, contemporary with the proto-Tardenoisian Sauveterrian, and a later, in which the Tardenoisian industry is accompanied by some hundreds of implements of sandstone, of which the *pic-plane* is characteristic, occurring for the most part on the habitation sites, and none at a depth greater than 70 cm. These *pic-plane* implements suggest (1) a greatly increased activity in wood-working and (2) that the Tardenoisian tribes, essentially mobile, used implements heavier than their hunting equipment when settling down for any length of time. Their occurrence here in conditions which made their pre-Campignian dating certain, show that this class of implement is older than has been thought, and contributes to discussion of the occurrence of Tardenois and neolithic together.

Diagonal Law of Birth-Rate Decline

IN a statistical study of the decline in the birth-rate in various European countries, by Mr. R. S. Barclay and Dr. W. O. Kermack (*Proc. Roy. Soc. Edin.*, 58, 55; 1938), several significant facts are brought out. It is first shown that for Scotland since 1860 and for England and Wales since 1841, when age at death began to be recorded, the specific death-rates in each age-group decrease at a constant rate for each age-group, giving what is called the diagonal law. The same method is then applied to birth-rates. This cannot be applied to Great Britain because the age of the mother at each birth has only just begun to be recorded. But from birth-rate data of Sweden, Denmark and Finland, when the specific fertility rates for any age-group (except 15–20) are expressed as percentages of a standard rate before the fall in the birth rate began, these percentages also conform to a diagonal law. This holds approximately for both the total fertility rates and the legitimate fertility rate. The diagonals for death-rates and birth rates are, however, at right angles, which means that the decline in fertility first began with the older women while the decline in mortality affected first the younger age-groups and then spread upwards. The wave of reduced fertility passes from one quinquennial age-group of women to the next in five years. The same linear relationships are indicated in Norway and France, but marked deviations occurred in all countries during and immediately after the Great War. This diagonal law is applied in predicting the fertility rates in England and Wales until 1951.

A New Strepsipterous Insect

MR. T. W. KIRKPATRICK, of the Amani Research Station, Tanganyika Territory, has published a notable paper on the above subject (*Trans. Roy. Entom. Soc. Lond.*, December 1937). The insect in question, *Corioxenos antestiae* Blair, parasitizes coffee bugs of the genus *Antestia* after the manner of a stylops. Since the work of the Russian observer, Nassonov, published in 1892–93, very little has been added to what is known of the biology of Strepsiptera. Knowledge is especially meagre of those forms which 'stylopize' Hemiptera, and Mr. Kirkpatrick's paper provides the only detailed account available of the biology and metamorphosis of a form which parasitizes members of this order. It is well known that the hosts of Strepsiptera often differ in their external characters from unstylopized examples, but *Corioxenos* produces no such effects. Its influence on the internal sexual organs, however, is very marked: female hosts are invariably infertile and the males are usually so. The male *Corioxenos* passes through eight instars before becoming adult, and each of them is figured and described. The adult male only lives for two to three hours, but during that time it is able to pair with a number of females. The females produce more than 3,500 triungulins apiece during a period of about three months.

Chilopoda of New Zealand

THE Chilopoda or centipedes of New Zealand form the subject of a revisional monograph by Mr. G. Archey, who is director of the Auckland Museum, N.Z. (*Rec. Auck. Inst. Mus.*, 2; 1936–37). Prior to the completion of this study, some 64 species of New Zealand Chilopoda had been named. The results of the present work, instead of adding to this list, have entailed the reduction of this number to 37 species. This reduction has resulted from the examination of many specimens of several of the species, which with a study of those characters hitherto regarded as of diagnostic value, has shown that such features fall within the normal range of variation of widely distributed species. Only a single new species is described. As regards their zoo-geographical relationships, the New Zealand centipedes appear to be more closely akin to those of southern Australia than elsewhere.

Absorption of Gas Bubbles in Wood Vessels

H Dickson and V H Blackman have recently published experimental observations on the absorption of bubbles of air, nitrogen and oxygen introduced into the xylem vessels of both living and dead tissues of *Impatiens parviflora* (*Ann Bot* New Series, 2 No 6 293, April 1938) The bubbles were found to decrease in size until they were dissolved in the cell sap of the surrounding tissues Rate of absorption varied the average sized bubble taking 12 20 minutes to be completely absorbed The disappearance of these artificially introduced air bubbles is attributed mainly to the increased partial pressures of the gases of the bubbles resulting from the high surface tension forces acting on the small bubbles No evidence was obtained to support the suggestion (P K Sen and V H Blackman *Ann Bot*, **47**, 663 1933) that increase in the partial pressure of nitrogen in the bubbles, resulting from the absorption of oxygen by the surrounding living tissues, plays any part, though the authors state that some such effect would seem inevitable The bearing of these results on the ability of cut flower shoots to absorb water, after the cut surfaces of their stems have been exposed to the air is discussed

Magnetic Susceptibility of Iron in Ferrohæmoglobin

THE iron in oxyhæmoglobin and carbon monoxide hæmoglobin is diamagnetic and the iron atom is bonded to six neighbours with covalent bonds The iron atom in ferrohæmoglobin has a magnetic moment about equal to that expected for a ferrous ion held by electrostatic bonds but somewhat larger than usual for ionic ferrous complexes With the technique now in use, hæmoglobin concentrations can be measured as accurately by magnetic methods as by the more tedious gasometric methods D S Taylor and C D Coryell (*J Amer Chem Soc*, **60**, 1177, 1938) have determined the magnetic susceptibilities per formula weight of iron in hæmoglobins as cow, 12 290 horse, 12,260 sheep 12 390 human, 11,910 all $\times 10^{-6}$ c g s units at 25° The magnetic moments for the hæmoglobins are calculated as 5 435 5 43, 5 46 and 5 35 Bohr magnetons respectively assuming independent iron atoms In an extensive study of cow hæmoglobin the susceptibility was found to be constant from individual to individual and to be unaffected by hæmolysis Normal blood and oxyhæmoglobin solutions contain hæmoglobin like compounds probably containing ferric iron, which do not combine with oxygen It was established that the hæmoglobin concentration determined from the carbon monoxide capacity after reduction agrees with that determined from the iron content The accurate determination of the paramagnetic susceptibility of the iron in hæmoglobin now makes it possible to determine hæmoglobin concentrations magnetometrically with high precision

Arrangement of Molecules in Mono- and Multi-Layers

IN an extension of their investigations of the arrangement of molecules in mono and multi layers, L H Germer and K H Storks (*J Chem Phys*, **6** 280, 1938) record observations by electron diffraction methods on layers of stearic acid and of barium stearate deposited on a chromium plated surface, and by electron transmission methods on layers of the same substances deposited on a thin foil of 'Resoglas' When the chromium plated block is dipped through a monolayer of either substance, a single layer of the substance is deposited on the chromium surface The hydrocarbon chains of such a layer are closely packed but arranged irregularly, and the axes of the chains are practically normal to the surface On each subsequent dipping of the block, *two* layers are deposited, and in these layers the molecules are regularly arranged in a characteristic crystal unit with chain axes normal to the surface When Resoglaz is dipped through mono layers, each dipping including the first results in the deposition of two layers, and the molecules are always arranged regularly in the characteristic crystal unit On 'Resoglaz the hydrocarbon end of the molecule is in contact with the support, whereas it is the barium or the carboxyl group which makes contact with the chromium Deposition of stearic acid on polished steel indicates an irregular arrangement of molecules in the first layer Presumably this irregularity in the first layer on a metal surface is due to interaction between the stearic acid and the metal The paper contains an interesting suggested extension of these methods to the investigation of boundary lubrication Another predicted extension is to the investigation of layers of adsorbed gas

Measuring Bridge for Conductimetric Titrations, etc.

WE have had an opportunity of using one of the measuring bridges Type *G M* 4140, designed by the Mullard Wireless Service Co Ltd, 225 Tottenham Court Road W 1 This is a very compact instrument made up in a strong metal box the cost being £12 12s With connexions to the mains and an earth resistances from 0 1 ohm to 10 megohm can be measured directly with the mains frequency of 50 cycles The balance point is very ingeniously read visually by means of an electron beam tube in conjunction with a high magnification pentode valve This arrangement gives very clear and sharp balance points, and the absence of galvanometers or telephones makes the whole lay out most compact and handy The electron beam indicator can be made very sensitive near the point of balance Several conductimetric titrations with various substances were made with a cell also supplied by the makers of the instrument, and it was found possible without any difficulty to attain an accuracy of 1 per cent, this accuracy being limited by the scale reading and adjustment by the milled head carrying a pointer It would be possible to increase the accuracy somewhat by a fine adjustment screw and vernier The results were equally good with low and high resistances The bridge potential is only 1 volt and hence it is probable that even with a frequency so low as 50 cycles per second, there is no appreciable polarization error in normal cases, when this voltage does not exceed the decomposition voltage of the electrolyte used With silver nitrate solution and silver electrodes, we found that an end point could not be obtained, since here the decomposition voltage is below 1 volt The makers supply a separate oscillator with a frequency of about 2500 cycles per second for use when polarization effects are noticeable, but we had no opportunity of testing this The instrument examined is also capable of application to capacity measurements, condenser loss measurements and inductance measurements It should prove a great service in technical laboratories, and also in research laboratories where the highest accuracy is not essential No great skill is necessary in order to obtain very good results

Oxford Museum of the History of Science

THE historic interest of the Old Ashmolean Oxford, and the association of the founder of the original *Musæum Ashmoleanum* with the pioneer promoters of the new philosophy whose names were inscribed as original fellows of the Royal Society have been referred to on many occasions in these columns, particularly in connexion with the unceasing labours of Dr R T Gunther to establish a Museum for the History of Science in the Old Ashmolean Building The purposes and scope of this Museum are not, however, widely known, so that the sequence of events which have led to the appeal for financial support in *The Times* of June 21 may be of interest

In 1924, the University accepted from Dr Lewis Evans the gift of a valuable collection of astrolabes and other astronomical and mathematical instruments The donor was a member of a remarkable family, responsible for a number of entries in the Dictionary of National Biography He was the brother of Sir Arthur Evans son of Sir John Evans and great grandson of the Rev Lewis Evans, F R S (1755 1827) who became mathematical instructor at the Royal Military Academy, Woolwich in 1799 and with whom the collection seems to have started The gift might presumably have been housed in the Science Museum of the University, in the building of which Ruskin played a large part But the donor had other ideas The old Ashmolean Museum had been diverted from its original purpose The collections of Elias Ashmole had been removed to more modern and commodious premises In the vacated building, the School of Geography and the offices of the 'Oxford Dictionary had found a temporary home Here Dr Evans saw a suitable site for his collection, and the University accepted the condition

In these circumstances of isolation, a museum however small, needs a curator, and in this case an enthusiastic and energetic curator was readily found in Dr R T Gunther, of Magdalen College The next step is easily foreseen A small museum under a keen curator has a natural tendency to grow especially when the contents are of this particular kind An obsolete instrument, which is a positive embarrassment in one place, becomes a valuable accession here This is not to suggest that additions have been accepted without judicious care, or that the resulting collection is not an interesting and valuable one The admission in the letter that it was difficult to forecast the position only a short time ago, must therefore, be taken as a proof of candour rather than of any sense of intelligent anticipation

It is candidly admitted that the University has other pressing needs , and in view of the recent comprehensive appeal on behalf of the University it seems a little difficult to understand how far the present letter claims an official character It is signed by the Chancellor and the Vice Chancellor , the other signatories are four Magdalen men and four Cambridge men, the last of the highest eminence in the scientific world but not perhaps very intimately acquainted with the financial position at Oxford In the circumstances, particular importance should be attached to the unofficial element, and the plea for the Museum of the History of Science should perhaps be treated strictly on its merits, which are no doubt considerable

An appeal of this kind raises however, the whole question of voluntary contributions for scientific and similar purposes Rightly or wrongly, Great Britain is committed at present to the system of voluntary hospitals One consequence is that the bulk of public benefactions is drawn into a single channel Very little money is left to supply the needs of culture and pure science, which elsewhere gain liberal support from voluntary sources Here the fund is notoriously inadequate, and this fact ought always to be borne in mind when competitive claims to public assistance are put forward The lack of means to carry on important scientific work is familiar to all those who have been connected with its administration Thus, though the position is now rather easier through the working of international organization, for many years the Seismological Committee of the British Association was sorely hampered for want of funds It is but fair to recall that the burden of keeping alive an infant science in Great Britain fell in that instance largely on the University of Oxford Another example may be found in that admirable institution, the Norman Lockyer Observatory at Sidmouth, which could enlarge its activities with ease were the necessary funds available It is needless to multiply illustrations of a general problem

The question arises, therefore, whether appeals to the public on behalf of individual institutions offer the most effective solution of this problem Even the hospitals have found the advantage of organizing a central fund from which a fair distribution can be made It seems possible that science also may have something to gain by similar action The Government Grant Fund administered by the Royal Society is useful within a restricted range, and the same body is enabled to do more by its own endowments, which are steadily increasing But still more could be done if the means were forthcoming Competitive appeals, the relative merits of which can scarcely be gauged by the public may not be the right method It seems possible that a unified scheme administered by a competent body might produce a larger fund and a fairer distribution in accordance with the true interests of pure science Applied science and industrial research are in a happier position, and the problem is less urgent in that field

It is to be feared that this suggestion even if it were found worthy of consideration, might not give much help in a case like that of the Oxford Museum of the History of Science Just as its interests are admittedly subordinate to the needs of the teaching departments, so in a wider scheme the claims of pure research would probably take the first place Hence the present appeal must in any event stand on its own merits, and the increasing interest taken in the history of science should ensure a satisfactory response to it Though the main responsibility of supporting this Museum will probably fall on Oxford, the signatories to the appeal are fully justified in inviting assistance from outside the University to ensure that the Museum is provided with the relatively modest amount required for its maintenance of the valuable collections which Dr Gunther has been so successful in bringing together, and to which he has devoted so much careful attention

International Engineering Congress at Glasgow

THE selection of Glasgow for the sessions of the International Engineering Congress, organized with the co-operation of the ten leading British technical institutions, not only enabled the delegates and members to visit the numerous works and industrial establishments in and around the City, but also afforded the opportunity of holding the Congress at the Empire Exhibition at Bellahouston, with its varied and extensive display of manufactures, machinery and plant. Fully a thousand members attended the Congress, representative of the United Kingdom, the Dominions, France, Germany, Italy, Belgium, Denmark, Finland, Hungary, the United States and other countries—about twenty in all.

The opening address on June 21 was delivered by the president of the Congress, Lord Weir, who declared that it is the province of the modern engineer to restore a balance of sanity in a world containing an order of society planned for the utter destruction of civilization, characterized by the minimum of international commercial intercourse, and in which the life of every individual is limited and conditioned by the constant fear of a potential enemy. "Against this sombre picture,' he said, 'wherein the law of the jungle appears to be the chosen principle of evolution, it is with relief that we can descry the compensating forces of science and reason."

Mr. John Colville, Secretary of State for Scotland, and Lord Elgin, president of the Exhibition Committee, also addressed the Congress and extended to the members a cordial welcome to the metropolis of Scottish industry, the latter emphasizing his view that at a moment when all the nations of the world are thinking how to protect themselves, "it is more important to think further as to what science can do and will do in making this place better than it has been—a place where we can meet together as friends."

The papers afterwards read at the meetings on June 21–23 dealt with such varied subjects as British shipbuilding, coal, municipal and industrial planning, developments in electrical engineering, the internal combustion engine, the iron and steel industry, international air transport, naval and mechanical construction in Italy, gas, and materials research, with one of appropriate local interest—the River Clyde and the Harbour of Glasgow.

Among some striking passages contained in these papers were the statements of Lord Sempill that the total mileage of airways which in 1919 was 3,000, to-day has attained a figure of much more than 300,000. Civil aircraft are now flying about 167 million miles, of which America accounts for 72 millions. The speed attained is as much as 450 miles per hour, and there is no reason why it should not be increased. An eminent French engineer, M. Mercier, president of the Union d'Electricité, stated that the total world production of electrical energy has been estimated at 310 milliard kwh. for the year 1929 and at 450 milliard kwh. for 1937. Far from having attained its limit, consumption of electricity is developing fully with very wide possibilities before it.

On the evening of June 21, the president of the Congress gave a dinner to the official delegates, which was followed by a civic reception in the City Chambers by the Lord Provost and Corporation to all the Congress members. Through the courtesy of manufacturing firms, numerous facilities were afforded for visits to local works and factories, while excursions were also made to centres of interest farther afield.

BRYSSON CUNNINGHAM

South-Eastern Union of Scientific Societies

Annual Congress

FOR its forty-third annual congress, the South-Eastern Union of Scientific Societies met at Worthing on June 21–25, a five days congress. At the inaugural meeting, Prof. Julian Huxley, who succeeded Prof. F. E. Weiss as president, took as the subject of his presidential address "Natural History, Taxonomy and General Biology". Naturalists are now engaged, he said, in tidying up and arranging the enormous number of insects and other forms of life, and those engaged in so doing call themselves taxonomists. There are more than five thousand kinds of two-winged insects in the British Isles and nearly as many beetles. Separate species of life already catalogued number somewhere about a million. Taxonomy is becoming one of the focal points of biological research. The staffs of the museums are overburdened with their share of the work. Local naturalists can take a part, and the Association for the Study of Systematics is endeavouring to form a panel of amateur workers. Prof. Huxley advocated detailed mapping of animal and plant life distribution. Evolution is going on all around us in the quiet country-side, just as much as in the deep sea, or the tropical jungle, although difficult to detect.

At the meeting of the Zoological Section Sir Edward Poulton gave one of his fascinating lectures on 'Lamarckian and Darwinian Conceptions of the Struggle for Existence", which was listened to with the attention due to one of so great authority. He was followed by Mr. J. Hornell, who read a paper on "Designing of Public Aquaria". After reviewing the mistakes made in the past in the aquaria at such places as Brighton, Southport, Blackpool and elsewhere, where amusement was mixed up with the attempts to teach science, he showed how he would design a future aquarium. Mr. Hornell was formerly director of fisheries to the Madras Government, and the erection under his guidance of the aquarium at Madras resulted in a great popular movement to study the contents of the tanks he installed.

The Re colonisation of a Burnt Patch at Cissbury" was the title of a paper by Mr B T Lowne The Jubilee and Coronation bonfires of 1935 and 1937 left a scar more than 50 ft in diameter with a thickness of some 8 inches of ash These sterilized the soil to some depth The creeping thistle was the first plant to establish itself followed by the blackberry Several plants not native to the spot made an appearance notably the evening primrose but this may have been carried to the spot in the footwear of one of the builders of the fire Late visits to the spot showed that thirty nine species of plants have established themselves and downland plants are gradually again growing there Mr Lowne also exhibited a hybrid between two species of geranium which he discovered on the Downs and found that the hybrids had bred true many specimens having been found

Miss F Gerard curator of the Worthing Museum showed maps of Sussex from the earliest times of map making including a copy of the Armada map and another of the Palmer map of 1587 The many changes in the coast line were clearly shown

Other papers of a high order were contributed amongst them being Ecology of the Selborne District by Dr C P Chatwin Recent Progress in the Study of Insect Migration by Dr C B Williams The Coastal Plain by Mr C T Caster and Mr E C Martin British Herbals of the 17th Century by Dr T A Sprague and A Proposed Survey of Chalk Springs and Bournes by Mr E H Edmunds

It was announced that John Selden s cottage known as Lacies at Salvington where Selden was born in 1584 had been offered as a freehold to the Worthing Corporation by Mr Alfred W Oke

The Union having been requested to arrange for the delivery of the Alexander Pedler Lecture of the British Science Guild now incorporated in the British Association this was entrusted to Prof H L Hawkins who took as his subject Humanity in Geological Perspective After discussing many outworn theories he said that he suspected that true geological knowledge is even now held but by the few and is brushed aside by those who have it but do not wish to own its teachings Truth chivalry and kindness are he said inconsistent with the struggle for existence but nevertheless the idealist who faces noble thoughts is a man Men can learn their capacity for appreciating wisdom shows that its acquisition is not beyond their powers And wisdom which makes men human is better than the rubies of material success that may leave him bestial

The excursions were very varied suiting all tastes visits to Cissbury Amberley Sompting the Broadwater Waterworks the Angmering Roman Villa Swanbourne and the Arun and the Highdown House Gardens having been arranged

A reception at the Town Hall was given to members by the Mayor and Mayoress Councillor and Mrs W C Birkett whose co operation in making the Congress a success was greatly appreciated by the Union

Scientific and Industrial Research in Australia

THE eleventh annual report of the Council for Scientific and Industrial Research, Commonwealth of Australia which covers the year ended June 30 1937, refers to the establishment of a Fisheries Section to conduct researches into Australian Fisheries problems This is at present housed in temporary quarters but a properly trained staff is being built up while the problems determining the location of the research station are being reviewed and an investigation vessel is under construction Experimental flights have already indicated that aerial observations can considerably assist the work of the investigation vessel Considerable progress was also made during the year in the provision of adequate laboratory facilities The Forest Products Laboratory was officially opened on April 7, 1937 the Viticultural Research Station, Merbein has been occupied and it was anticipated that the headquarters laboratories and experimental cool stores of the Section of Food Preservation and Transport and the new Animal Health Laboratory would be ready for occupation at the end of 1937

The Division of Plant Industry has continued its investigation into plant pasture problems as well as of physiological diseases of fruit in the field and disorders following storage Evidence has been obtained that high soil temperatures increase resistance to pest seedling development of flag smut in certain varieties of wheat and lowers it in others In the fumigation of seed beds for control of downy mildew or blue mould of tobacco, benzene vapour always gave the best results and attention is being turned to control under field conditions The Division of Economic Entomology has given much time to the sheep blowfly pest including studies both of the sheep and the flies as well as the prevention and treatment of strike Search has been made for substitutes for lead arsenate in insecticides for codling moth sprays and a good deal of the Division s time has been occupied with work on the biological control of noxious weeds as well as on chemical methods of weed control Investigations by the Animal Health laboratories have again ranged over a wide field including bovine mastitis studies in fleece chemistry and fibre measurement fertility in sheep dairy products research and in addition the Animal Nutrition Laboratory at Adelaide has been responsible for investigations on phosphorus metabolism of sheep and on coast disease

The Forest Products Division s investigations also cover a wide field from the seasoning of timber timber physics, wood structure and utilization to the preservation of wood where the value of arsenicals as termiticides in Australia and of sodium silicofluoride for protection against *Lyctus* attack has been established Many important investigations have also been carried out at the Viticultural Research Station on irrigation and drainage as well as by the Food Preservation Section, including investigations on chilled beef such as loss of bloom, on diseases of bananas and their control, citrus packing house problems, including the colouring of citrus fruits, and problems relating to the storage and diseases of apples, pears, plums, peaches, etc

Science News a Century Ago

Jean Marc Gaspard Itard (1775 1838)

July 5 marks the centenary of the death of this famous pioneer in otology who was born in 1775 at Oraison a small town in Provence At nineteen years of age, he became assistant to the celebrated surgeon Larrey at Toulon and afterwards accompanied him to Paris where he studied medicine under Pinel and Corvisart He qualified with a thesis on pneumothorax and shortly afterward was appointed physician to the Institute for Deaf Mutes where he gained a great reputation by his detailed study of the idiot boy known as the Sauvage de l Aveyron His chief work on the composition of which he spent eleven years entitled Traité des maladies de l oreille et de l audition appeared in 1821 and a second edition was published posthumously in 1842 He invented an acoumeter which was the first instrument of its kind as well as a form of Eustachian catheter and an instrument for the improvement of hearing He was also the author of articles on stammering intermittent fever and dropsy and translated Willich s book on domestic hygiene In 1816 he became joint editor of the *Journal Universel les sciences médicales* and in 1822 of the *Revue Médicale* while in 1832 he was made editor of the ' Dictionnaire de Médecine

Launch of the *Robert F Stockton*

On July 7 1838 Lairds of Birkenhead launched the iron screw steamer *Robert F Stockton* which being sent to the United States the following year became the first screw driven vessel to be used for practical purposes in that country She was built to the order of Captain R F Stockton (1795 1866) of the United States Navy and fitted with the screw propeller invented by John Ericsson She was 63 4 ft long 10 ft beam 7 ft deep 33 tons register and 33 horse power She was fitted with a two cylinder engine driving the propeller shaft directly and not through gearing In January 1839 she carried out trials in the River Thames when she successfully towed four coal barges from Southwark to Waterloo Bridge Referring to her trials *The Times* said that they appeared quite conclusive as to the success of this important improvement in steam navigation The vessel was sent to America under sail and afterwards was used as a steam tug on the Delaware and Raritan Canal being renamed the *New Jersey*

Supply of Pure Milk

On July 7 1838 the *Mechanics Magazine* contained a communication from J Fordred directing attention to an essay on milk supply by M Barreul recently published in Paris The essay contained a remarkable review of the methods used for adulterating milk Some of the more wealthy inhabitants it said who obtained their milk direct from the dairies at a good price had it pure but the mass of milk sold in Paris was more or less adulterated with water brown sugar flour or emulsion of sweet almonds It was suggested therefore, that the authorities should ordain that no milk should be sold except in sealed measures and that in each quarter of the city one or two pharmacists should be charged with the duty of examining the milk from time to time Penalties were proposed for every fraudulent alteration in quality or quantity

University Events

Cambridge —Dr A J Bradley has been appointed assistant director of research in crystallography and Dr J E Driver University demonstrator in the Department of Chemistry

The Vice Chancellor gives notice that the John Humphrey Plummer professorship of mathematical physics will be vacant on October 1 by the resignation of Prof R H Fowler Preference will be given to candidates whose work is connected with theoretical atomic physics The stipend of the professor is £1 200 a year or if he holds a fellowship with dividend £1 000 a year Candidates for the professorship are requested to communicate with the Vice Chancellor and to send him on or before July 20 ten copies of any statement or testimonial which they desire to submit to the electors If testimonials and references are sent, they should not taken together exceed four in number

Dr B C Saunders University demonstrator in chemistry has been elected to a fellowship at Magdalene College Dr Saunders was placed in the first class of the Natural Sciences Tripos Part I in 1924 and the first class in Part II of the same Tripos in 1925 in which year he was elected to the Beatson Scholarship at Pembroke College Since 1931 he has been Charles Kingsley lecturer and director of studies in natural sciences and medicine at Magdalene College

J R F Jeffreys of Downing College has been elected to the Sheepshanks Exhibition for 1938

H Davenport of Trinity College has been approved for the degree of doctor of science

London —Sir Robert Pickard has been re elected vice chancellor for the year 1938 39 Dr A M H Gray has been appointed deputy vice chancellor for the same period

Dr J D Boyd has been appointed to the University chair of anatomy tenable at the London Hospital Medical College as from the beginning of next session Since 1937 he has been University lecturer in anatomy in the University of Cambridge

It has been resolved that on the occasion of the celebration of Foundation Day 1938 the following honorary degrees among others should be conferred Sir Charles H Bressey the degree of doctor of science (engineering) Sir Robert Ludwig Mond the degree of doctor of science Prof A W Pollard the degree of doctor of literature

Prof J H Clapham has been appointed Creighton lecturer for the year 1938 39

The following doctorates have been conferred D Sc in anatomy on Prof Thomas Nicol University professor at King s College D Sc in biochemistry on Mr B C J G Knight University College D Sc in botany on Mr Hugh Dickson Imperial College—Royal College of Science

Oxford —J D Lambert has been elected to an official fellowship as lecturer in natural science at Trinity College in succession to Prof C N Hinshelwood

Sydney —At the Annual Commemoration Ceremony on May 14 the opportunity was taken of presenting to Dr W L Waterhouse acting dean of the Faculty of Agriculture of the University of Sydney the Farrer Memorial Medal This is the third occasion on which the medal in honour of the world famous wheat breeder has been awarded

Societies and Academies

Paris

Academy of Sciences, May 9 (*C R*, 206 1333 1420)

Louis Couffignal A problem of abstract mechanical analysis the theory of reduction, result of mechanical functions

R de Misès The infinitesimal element of order *n* of a skew curve

Husni Hamid *The hypercongruence of Euclidian space of* $n + 1$ dimensions

Béla de Sz Nagy Series of multiply monotone factors

Alexandre Ostrowski Some transformations of the series of Liouville Neumann

Mlle Marie Charpentier The Peano points of certain systems of differential equations

Alexandre Ghika The determination of analytical functions

Silvain Wachs Some properties of pseudo conformal transformations with an invariant frontier point

Étienne Œhmichen The teachings of natural flight and their applications to flying machines capable of hovering in the air

Jean Tilho Remarks on the heliostat

Assène Datzeff The mean distribution of the electrons in a complex atom

Benjamin de Jekhowsky A criterion for the identification of small planets A simplification of the methods of calculation of the criterion of Luc Picart

V A Nicolsky Method of calculation of plates of unequal moments of inertia

Aurelio Marques da Silva The materialization of a photon in the field of an electron

Jean Virgitti The theoretical study of a transport of ions by a current of vapour used for obtaining high potentials

Nicolas Perakis, Tryphon Karantassis and **Leandre Capatos** The measurement of the atomic (magnetic) moment of tetravalent rhenium

Yeou Ta The repetition of the whole of the *vibration spectrum of organic molecules in the neighbourhood of each of the frequencies (CH) of vibration, fundamental or harmonic*

André Guinier The diffusion of X rays under very small angles applied to the study of fine particles and to colloidal suspensions

Georges Carpéni The preparation, electrometry and ultra violet spectrography of glucohepto ascorbic acid

Pierre Bonneman and **Marc Bassière** The condensed phosphoric acids The polyphosphates

Félix Trombe The isolation of metallic europium The electrolysis of europium chloride in the eutectic mixture of potassium and sodium chlorides with a cadmium cathode gives a cadmium europium alloy from which the cadmium can be removed by heating in argon under reduced pressure at carefully controlled temperatures The final product contains 98 per cent of europium

Roger Lauffenburger and **Michel Brodsky** Study of the system $Na_2HPO_4 + 2NH_4Cl \rightleftarrows 2NaCl + (NH_4)_2HPO_4$

Jean Baron and **Paul Laffitte** The inflammation of normal propyl ether The pressure temperature of inflammation curves are analogous with those of ethyl ether, and, as was found with the latter, the addition of nitrogen to the mixtures of oxygen and ether lowers the temperature of inflammation

Gustave Vavon and **Roger Mathieu** The hydrogenation of halogen derivatives by platinum black

Victor Madsen The Caledonian chain of northern Greenland

Christian Poulsen The Ozarkian in Greenland

Georges Choubert and **Louis Neltner** The Pre Cambrian of the western Anti Atlas

Jean Feldmann and **Mlle Geneviève Mazoyer** The *ioduques* of *Asparagopsis armata*

Jean Renaud The existence of the dicaryon in a *Saccharomyces* isolated from the vine

Mlles Berthe Delaporte and **Nadia Roukhelman** The presence of thymine in the nucleic acid extracted from yeast Cytological and chemical researches

Pierre Chouard The experimental production of buds under the influence of the heteroauxins

René Souèges The embryogeny of the Illecebraceae [Scleranthaceæ] The development of the embryo in *Scleranthus perennis*

Jean Cuzin Evidence of the remarkable constancy in the regime of growth in the germination of pollen

Mme Cécile Sosa Bourdouil The comparative composition of spores and pollens of vascular plants

Raymond Cahen and **Mme Andrée Tronchon** The action of zinc on the œstrogenic effects of folliculine in the ovariectomized rat Zinc chloride increases the intensity and prolongs the duration of the œstrogenic effects of folliculine in the ovariectomized rat provided that the ratio of zinc to hormone lies between certain limits

Mme Véra Dantchakoff The mechanism of the sexual deviations resulting from (*a*) treatment with testosterone (*b*) free martinism (*c*) tumours of the suprarenal capsule (virilism)

Auguste Sartory, René Sartory and **Jacques Meyer** The influence of certain water soluble vitamins on the velocity of growth of various cocciform bacteria

André Boivin and **Mme Lydia Mesrobeanu** The chemical nature and biological properties of the *Vi* antigen of the typhoid bacillus

INSTITUTE OF PHYSICS (MANCHESTER AND DISTRICT BRANCH), July 4–5 —Conference on Elasticity and Plasticity to be held in the University of Manchester *

MUSEUMS ASSOCIATION, July 4–9 —Annual Conference to be held in Belfast

Appointments Vacant

APPLICATIONS are invited for the following appointments, on or before the dates mentioned

VEGETABLE SPECIALIST in the Punjab Agricultural Service Class I—The High Commissioner for India, General Department, India House, Aldwych, London, W C 2 (July 7)

LECTURER IN PRODUCTION ENGINEERING in the Dudley and Staffordshire Technical College, The Broadway, Dudley—The Principal (July 7)

JUNIOR LECTURER IN ELECTRICAL ENGINEERING in the Military College of Science, Woolwich, S E 18—The Commandant (July 8)

LECTURER IN MECHANICAL ENGINEERING in the Central Technical College, Suffolk Street, Birmingham, 1 The Chief Education Officer (July 9)

LECTURER IN MECHANICAL ENGINEERING in the North Staffordshire Technical College—The Clerk to the Governors, Education Offices, Town Hall, Hanley, Stoke on Trent (July 9)

LECTURER IN CHEMISTRY and LECTURER IN PHARMACEUTICAL CHEMISTRY in University College, Nottingham—The Registrar (July 11)

ASSISTANT LECTURER AND DEMONSTRATOR IN CHEMISTRY in King's College for Household and Social Science, Campden Hill Road, London, W 8—The Secretary (July 11)

ASSISTANT LECTURER IN THE DEPARTMENT OF BUILDING, Huddersfield Technical College—The Principal (June 13)

HEAD OF THE BIOLOGY DEPARTMENT, Huddersfield Technical College—The Principal (July 13)

JUNIOR LECTURER IN SCIENCE in the Royal Military Academy, Woolwich, S E 18—The Under Secretary of State (C 5), The War Office, London, S W 1 (July 16)

UNIVERSITY LECTURER IN MATHEMATICS in the University of Cambridge—Dr H M Taylor, Clare College, Cambridge (July 16)

PLUMMER PROFESSOR OF MATHEMATICAL PHYSICS in the University of Cambridge—The Vice-Chancellor (July 20)

PROFESSOR OF PHYSIOLOGY in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 88a Gower Street, London, W C 1

International Science

FOR several years past we have been familiar with the spectacle of eminent men of learning being forced to leave their work either on racial grounds or because they do not accept particular political, religious or other limited views The list of men of science in Austria who have recently been dismissed from their posts (see NATURE, June 18, p 1101, July 2, p 32), is a pertinent reminder that this state of affairs not only persists, but is even extending, and that the work of the Society for the Protection of Science and Learning needs continued and enhanced support

Important as is the work of relieving the distress entailed by such proscriptions and establishing the victims in conditions under which they can resume their studies and benefactions to mankind, there are other insidious effects which may have even more serious consequences to the world if unchecked No unprejudiced person questions the real impoverishment of science, for example, in hose countries from which the evictions on such grounds have occurred What is less apparent, however, is that the loss is one from which the whole world of science and learning suffers

A striking example of this is to be found in the recently published review of the work of the Rockefeller Federation in 1937 From the beginning of its activities twenty-five years ago, the Foundation has been guided by the objective set forth in its charter: "The well-being of mankind throughout the world." The trustees have endeavoured to maintain the work of the Foundation on an international plan without consideration of political doctrines or creeds, believing that in a programme based on the advancement of knowledge it is imperative to disregard the geographical boundaries which arbitrarily and often unhappily divide the world into a patchwork of senseless antagonisms In its search for high talent and promising opportunities, the Foundation has assumed that national frontiers are not the forbidding barriers they purport to be

In recent years serious and increasing difficulties have been encountered in pursuing this policy As Raymond B Fosdick, president of the Foundation, points out, objective scholarship is possible only where thought is free, and freedom can exist only where there is tolerance and where there are no prohibitions on the inquisitive and questioning mind

The progressive disintegration of creative scholarship, particularly in the social sciences and the humanities, which the world has recently witnessed in several countries, has already affected the programme of the Foundation In some fields it is now profitless to go where it formerly went, and its work is stopped at some frontiers because behind them the search for truth by eager and sceptical minds has been made impossible.

It needs no profound acquaintance with the detailed activities of the Foundation and its many benefactions to mankind in all countries to realize the gravity of a situation which can draw such words from the president of the Rockefeller Foundation In the last analysis, knowledge cannot be nationalized. Successful embargoes cannot be maintained against the export or import of ideas We are all of us, under whatever national flag, the joint beneficiaries of the intellectual property of mankind Science cannot but have a single aim and language in the discovery of truth or it ceases to be science

Nowhere have the dangers of the present situation been more plainly set before scientific workers It is bad enough that the activities of such an organization as the Rockefeller Foundation should be circumscribed and certain countries deprived of the services it could render This however is not the concern of those nations alone for the whole world is impoverished by this state of affairs Scientific progress depends on co operation and anything which limits the freedom of scientific work or scientific workers because they do not accept particular political or religious views whether generally or in limited areas is detrimental to the advancement of knowledge and the progress of mankind The contact between keen and untrammelled minds of men of all races supplies one of the most indispensable stimulants to scientific progress and we hamper it at our peril

The fears concerning intellectual freedom which Prof A V Hill expressed four years ago in his Huxley Memorial Lecture on The International Status and Obligations of Science have indeed been justified and it cannot be said that scientific workers as a whole have heeded his warning Many of them still forget that freedom of thought though fairly and hardly won is not a permanent and inevitable attribute of science but has to be maintained by further struggle The coercion of scientific workers to specified political opinions has already lowered the standard of scientific honesty in those countries and if unchecked may bring science itself into contempt Nor would it be hard to find evidence of forces in the Anglo Saxon communities which are working to hinder research to destroy free thought and to strike at the root of all opinion not congenial to authority

This therefore is no time for shallow complacency for self congratulation at the comparative freedom of thought to be found in one country rather than in another Scientific workers cannot be content to concern themselves solely with the advance of a science within their own national frontiers That way lies impoverishment and ultimate stultification The advancement of science no less than the continual progress of mankind demands that the liberty lost anywhere shall be regained Science and learning must recognize that they exist not only for their own sake not only for what they can do for the material welfare of mankind but chiefly for the fact that they alone seem to be truly international and capable of transcending national follies

Among the welcome signs that scientific workers are coming to recognize the gravity of the situation are the resolutions passed at the Indianapolis meeting of the American Association for the Advancement of Science and the response they have already received The first resolution affirming the independence of science of national boundaries and races and creeds and asserting that science could only flourish where peace and intellectual freedom were found extended an invitation to the British Association for the Advancement of Science to co operate not only in advancing the interests of science but also in promoting peace among nations and intellectual freedom The same resolution also declared that an examination of the profound effects of science upon society was one of the objectives of the Association

The second resolution referred even more specifically to the inroads being made upon intellectual freedom and declared emphatically that if the existing liberties won through ages of struggle and at enormous cost were lost or seriously impaired there could be no hope of continued progress in science or even of lasting material welfare The suppression of independent thought and its free expression was denounced as a major crime against civilization and the executive secretary of the Association was requested to raise with the British Association the question of co operation so that the combined scientific forces of America and Great Britain should act as a united world intellect

From these resolutions there have already been derived a number of concrete proposals such as the formulation of a set of fundamental scientific principles of an ethical nature and of the maximum number of inviolable methods of international intercourse and co operation among scientific workers as well as the planning of machinery for giving effect to such proposals Progress in such matters however is determined largely by the extent to which individual scientific workers are prepared to contribute both interest and active support Upon them depends mainly whether or not such matters figure prominently or not at all in the proceedings of the forthcoming meeting of the British Association

If the present drift is to be arrested and science and learning are to regain everywhere the immunity from interference or persecution to which they have been regarded as entitled in all civilized communities for several centuries it will not be by the efforts of a minority of scientific workers Science will only be re established in its unique place among the interests of mankind when scientific workers everywhere recognize their responsibilities and are prepared to make fresh sacrifices in the cause of intellectual freedom They must educate their fellow citizens to the realization that science is a common interest of mankind, and that whatever may be the barriers or the difficulties or the struggles between them, civilized societies must accord a certain immunity and tolerance to those engaged in scientific discovery and learning

Besides this, there must be a widespread recognition by scientific workers of the normal conditions of tolerance and immunity for scientific pursuits in a civilized State These restraints—not to meddle with or be dominated by divinity, morals, politics or rhetoric must be clearly understood and firmly accepted by scientific workers The loyal acceptance of such a code of ethics or discipline is all the more important to-day, not only if objective research in the social sciences is to be pursued, but also if what is often termed the frustration of science is to be overcome Scientific thought can no more exert its full weight than objective research be pursued unless scientific workers maintain most scrupulously their intellectual honesty and independence of political pressure The discipline of professional ethical codes, no less than the intellectual or technical excellence of the work carried out, is an important factor in establishing confidence in the integrity and impartiality of the results obtained

Scientific workers cannot afford to be indifferent to these matters They should be willing to make the effort both as men of science and as citizens, and to accept the challenge now thrown down to them Unity in defence of full freedom of thought, formulation and acceptance for themselves of the inevitable restraints demanded in a civilized community for orderly progress, refusal to allow any external system of thought or institution to dictate their decisions or activities, and promotion by all means in their power of the international exchange of ideas and its accompanying stimulation of thought are some of the necessary steps Given these desiderata, it will not be long before fresh victories are won for intellectual freedom, before the restraints on scientific intercourse are broken down and science is able to assist all nations to deal creatively and constructively with the great problems which everywhere confront us to-day

A Chapter in the History of British Botany

Sixty Years of Botany in Britain (1875-1935): Impressions of an Eye-Witness By Prof F O Bower Pp ix+112+14 plates (London Macmillan and Co, Ltd, 1938) 10s 6d net

ALL Prof Bower's books have been characterized not only by their clearness of style but also by a power of transmitting to the reader the interest of the writer. This sense of the enjoyment which the author has experienced in the writing is specially evident in the present book, which gives in vivid outline the history of an important phase in the development of botany in Great Britain In the period of which it treats, an almost revolutionary change was effected from the preceding purely systematic work to the aspects of botany familiar in our modern universities It was well worth while having the facts recorded, but this book is much more than a historical statement The history is strung on an equally interesting thread of autobiography, for Prof Bower not only lived through the whole period of which he writes, but also took an active part in its events. As the sub-title indicates, we are throughout receiving the impressions of an eye-witness Thus the reader is led on with sustained interest, grateful for the first-hand pictures he obtains of personalities and their work and sometimes a little regretful that he does not get more This artistic reserve, together with the clarity of the writing, makes the reading of the book not only profitable but also a real pleasure

As a boy at home and at a public school, the author was interested in natural history and especially in botany When he passed hopefully in 1874 into the University of Cambridge, he found the science almost dead, although the beginning of a revival was evident before 1879 in the private teaching of Vines It was from the active botanical schools of the Continent that the new botany came belatedly to Britain and, like others who were concerned in its introduction, Bower went abroad to work in the laboratories of Sachs and De Bary Reform in university teaching of the subject, on the other hand, came through Huxley at South Kensington, and Prof Bower gives us glimpses of the life of a young botanist in London in 1880-85. He became responsible for the botanical classes instituted by Thiselton-Dyer in Huxley's department, and there was active research work in the recently established Jodrell Laboratory in Kew Gardens. In 1885 Bower was almost commanded by Sir Joseph Hooker to take on the duties of the regius chair of botany at Glasgow, which he held for forty years. Botany was by then established on the new lines in England, but the work was still in great part to be done in the Scottish universities. The progress of the department at Glasgow is a good illustration of what took place in other universities.

In the course of the historical account, we have estimates of many great figures; of Hooker, Sachs, De Bary and Huxley among the seniors, and then of the younger men chiefly concerned in the movement. The brief accounts are accompanied by good portraits. It will be a revelation to many how much vital stimulus botany owed to men of whom one tends to think chiefly as administrators. This is particularly true of Thiselton-Dyer's part in the movement, but also holds for Vines and Balfour. The story of the foundation of the *Annals of Botany* by the latter is told in full. In connexion with the progress of fossil botany, we have personal impressions of Williamson, Scott and Kidston. This subject is taken as one illustration of the progress of branches of botany in Britain. It is balanced by a short consideration of the emergence of pure physiology in the botanical departments of the country, headed by Cambridge, where Francis Darwin and Gardiner were the initiators. Space will not allow of adequate comment on a chapter entitled 'The Morphological Kaleidoscope", which, as the author points out, is written in somewhat more technical style than the rest of the book. Here also the changes in point of view, the discoveries which "jogged the morphological kaleidoscope" and brought out new patterns in the study of the evolutionary morphology of land-plants, are made significant by being taken from Bower's own scientific experience.

A concluding chapter sums up the story sketched in the book, estimates the present state of botany in Great Britain, frankly recognizing the decline of interest in morphology, and looks with breadth of view and hopefulness to future progress both in pure botany and in its practical applications.

Prof. Bower has given us a valuable book which may interest many in addition to professional botanists. It should be available for the students in every botanical department. In proportion to their youth, readers will be removed from any personal contacts with the small body of pioneers who laid the foundation of the differentiated, perhaps over specialized, science as it is now found in our universities. Prof. Bower has been able to write as an eye-witness of these men and their work and has done this so vividly that we can realize how the botanical departments in which we work and the conditions we take for granted have come about. This is the book's immediate value; but the data it contains may prove invaluable to some future botanical historian. Those who introduced what was then called the 'new botany' were united in enthusiasm and in a sense of adventure, the thrill of which persists in these pages. What may be read between the lines, but is worth while making explicit, is the great part played by Prof. Bower himself, not only in the early stages of the movement, but also in carrying its spirit on to a later period. The reviewer can speak gratefully of the stimulating atmosphere which radiated from the professor in the still primitive department at Glasgow in the early 'nineties. As he can now realize, this was the direct outcome of the new spirit in investigation and teaching which came into botany in Great Britain in the 'seventies, and the history of which is the theme of this book.

W. H. L.

Research in the Antarctic

South Latitude

By F. D. Ommanney. Pp. xi + 308 + 16 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1938.) 9s. 6d. net.

EVER since Dr. Stanley Kemp, as director of research to the Discovery Committee, began in 1924 to get his staff together, the Natural History Museum at South Kensington has seen the coming and going of a group of young scientific men, for the most part biologists, collected from the universities of England, Scotland, Wales and Ireland. They would spend a few months at the Museum and then disappear for a year or two, to return, looking somewhat weather-beaten, accompanied by piles of packing-cases and casks (not always odourless) to arrange and study their collections in an iron shed at the back of the Museum, and to produce the long series of "Discovery Reports" which have been noticed from time to time in the pages of NATURE. Thanks to these reports, the Antarctic Ocean is becoming the best-known, from a scientific point of view, of all the Seven Seas. About their work these young men were always ready to talk to us, about the Antarctic Convergence, or the corpora lutea of whales, or the migrations of krill, but of their personal experiences we could hear but little. Yet, sometimes, over a pipe, one did get the impression that scientific research in the Antarctic was a man's job. Now, however, they have found a worthy spokesman.

Dr. Ommanney has the gift of arresting and vivid description; he has looked upon men and beasts and things with an observant and sympathetic eye; and he has the sense of humour to perceive the ridiculous in himself as well as in his companions. He does not dwell too long or too exclusively on the discomforts and hardships, but he does make us feel in some measure what it meant to step from teaching biology to first-year medical students to the gigantic horrors of flensing. Some of his pages are not for the squeamish, but if he is a realist, he is not of the type that is blind to the beauty beside the ugliness in Nature or to the nobility that lies behind the meanness in the spirit of man. Ommanney was one of the survey party of six men who were lost for ten days on King George Island in the South Shetlands, and tragedy was only missed by a hair's breadth. The story of their experiences is as moving as anything that has been told us from the Antarctic, and none the less so because they were not out to make a sporting 'record' but were doing a bit of sober and humdrum scientific research.

Although this book touches only incidentally on the scientific work that the author and his colleagues were doing, it does preserve many details that may be missed in more formal reports. The choking stench and deafening clamour of the penguin rookeries, the loathsome slumbers of the sea-elephants on the beaches, the dignified albatrosses on their nests—the ecologist must not forget these in his picture of antarctic life, while the student of animal behaviour will note the apparent inability of seals and penguins to concentrate attention for more than a few moments on anything lying outside the daily routine of their lives. It may be true that "the elephant never forgets", but the sea-elephant seems unable to remember for five minutes that he has watched one of his companions being butchered within a few yards of him.

The Colonial Office has at its disposal to-day not only the finest ship ever built for oceanographical research, but also a team of some of the most experienced oceanographers in the world; just how experienced, Ommanney has made clear to us in this book. It is much to be hoped that good use will be found for both when the present programme of research is brought to an end.

Psychiatry from the Behaviourist Point of View

A Biological Approach to the Problem of Abnormal Behavior

By Dr. Milton Harrington. Pp. 459. (Lancaster, Pa.: The Science Press Printing Co., 1938.) n.p.

THE disadvantages of the psychological approach to mental illness, the difficulty in proving facts, the prolonged treatment during which the patient is under the influence of the physician and the unpalatable theories of the psycho-analysts, have driven many to seek a basis for psychiatry elsewhere. It is inevitable that those who turn away from psychological theories should return to the obviously firm facts of physiology, and to such the investigations of Pavlov and the behaviourists are a gift from the gods.

Dr. Milton Harrington has already written a book in which he criticized the structure and theory of psycho-analysis ("Wish-hunting in the Unconscious", Macmillan, 1934) and in his present book we have the second of a triology. Here his efforts have "not been to present new evidence bearing on the problem of abnormal behaviour, but to bring together into the form of a theory, the important facts at present known to us, thus consolidating the gains already made and preparing the way for further progress". (The third book which will complete his triology is to be on treatment.)

It is obvious that with such an intention nothing new or strange will be found in his book. Moreover, the author does not take an entirely behaviourist point of view, but is willing to recognize consciousness and to use what he thinks is good in the old psychology. He thus obtains the best of both possible worlds, and by utilizing familiar physiological and psychological facts, he describes a psychophysiology upon which he constructs his psychopathology. Two thirds of the book are devoted to the psychophysiology and a third to the psychopathology. It is described in an interesting way with a facile style, and the whole is logically developed. One feels, however, a certain poverty of material and indeed the behaviourist's explanations are so obvious that any attempt to expand them makes a book rather laboured Dr Harrington makes the most of his material and his description of the Law of Confluence by which it is possible to explain conditioning reinforcement inhibition and the production of symptoms all by one principle is most interesting and valuable

When we come to the psychopathology we cannot help feeling unsatisfied Nor does it offer as all pathology should any fresh basis upon which to construct treatment It is doubtful whether we can explain for example the appearance of claustrophobia simply by conditioning The claustrophobic seldom give a history of repeatedly being shut in closed spaces and even if one or two terrifying instances will suffice to condition the child (as recent work suggests) the innumerable instances of harmless enclosure in daily life should neutralize them In fact one can scarcely live without going into lifts and so on every day and yet someone who has done this without difficulty for years may suddenly become frightened of them The author's explanations of paranoid delusions given on page 422 are not very satisfactory and merely echo the old traditional views If delusions could arise so easily they would be a great deal more common than they are to day

In spite of these criticisms the book is sound and no one can do other than profit from reading it There are very few mistakes—the most obvious is on page 343 where the writer mentions an innate sense of modesty and one wonders if he really believes that modesty is inborn and not acquired

Dr Harrington is to be congratulated on attempting to found a behaviourist psychiatry and if it is far from complete it is because he is bound by limitations of his own seeking No doubt he feels it is better to build a small safe structure than a towering construction of doubtful theory CLIFFORD ALLEN

The Universities Yearbook

The Yearbook of the Universities of the Empire 1938
Pp xlv + 1154 (London G Bell and Sons Ltd 1938) 15s net

THE first Congress of the Universities of the British Empire held in London in 1912 resolved that the time had come for establishing a permanent centre of information to carry on the good work begun by the Congress of weaving a fabric of mutual knowledge and understanding Thus originated the Universities Bureau of the British Empire and the Yearbook the compilation of which is one of its most important tasks In addition to being a who's who and a what's what for the universities a shop window for the wares they have to offer and a summary record of their annals it brings together in a series of appendixes a heterogeneous mass of data relevant to the interests of their members actual and prospective

Such a compendium has a tendency to become unwieldy and this year the appendixes now covering 240 pages have been rearranged in a more logical sequence than heretofore facilitating quick reference They deal with such matters as admission to universities students from abroad open post graduate scholarships admission to professional careers associations of students of teachers and of other people interested in higher education and research centres of scientific research and information libraries universities of the United States Anglo American professorships international organizations

Lastly there is a bibliography admission to which is jealously restricted Perhaps a little more latitude might be allowed for new publications for as long as they are new for example the publications of the International Institute Examinations Enquiry Committee (only one of which is mentioned) the N U S congress report entitled Graduate Employment and Prof Ginsberg's address to the British Association last year

In this year's issue appears for the first time the annual report of the executive council of the Universities Bureau The publicity thus given to the Bureau's proceedings is doubly acceptable by reason of the fact that the report includes a summary of the proceedings of the Committee of Vice Chancellors and Principals of the Universities of Great Britain and Ireland lineal descendant of the committee constituted twenty years ago in response to Lord Balfour's appeal to the universities to establish a body which should not only represent them vis à vis the Government and in their relations with the universities of other nations but also should be an organ of expression to voice their desires and aspirations The list of subjects discussed by the Committee (p xxxi and again on pp 17 18) is a long one, most of the items being of minor importance It does not appear whether any of them were matters referred to the Committee by Government departments, as contemplated in Lord Balfour's appeal

Contemporary Indian Philosophy

By M K Gandhi, Rabindranath Tagore, Swâmi Abhedananda, K C Bhattacharyya, G C Chatterji Ananda K Coomaraswamy, Bhagavan Das, Surendranath Dasgupta, Hiralal Haldar M Hiriyanna S Radhakrishnan, R D Ranade, V Subrahmanya Iyer, A R Wadia Edited by Dr S Radhakrishnan and Prof J H Muirhead (Library of Philosophy) Pp 375 (London George Allen and Unwin Ltd , 1936) 16s net

IT is for the mutual benefit of Eastern and Western philosophers that such books as the present are published A clarification of Indian thought is just as important to Indians themselves as to the growing number of European scholars who make a technical study of Indian thought Of the fourteen thinkers who contributed to the present volume Gandhi and Tagore belong to Indian national life, and their messages are incorporated more for their moral influence than for their export value But the essays of the other writers provide much food for reflection

Meditating On the Pertinence of Philosophy , Dr Coomaraswamy suggests that the highest wisdom is obtainable by finding what is common to different religions and by constructing a rational metaphysics on these common elements An example of the method proposed is given in a comparative study of the idea of immortality Discussing ' The Spirit in Man ', Sir S Radhakrishnan reconciles theism and absolutism But both are rejected by Prof Wadia, as giving no explanation of evil, in favour of pragmatic idealism The suggestive study of Prof Dasgupta on The Philosophy of Dependent Emergence ' and Prof Hiriyanna's essay on The Problem of Truth" will be read with much interest, while Prof Ranade's contribution, in which he proposes to reach truth by a critical interpretation of the great philosophers, is perhaps the most original of the series An excellent study of Vedantic philosophy is given by Subrahmanya Iyer, who discusses *maya* (illusion) and the three states of the soul (waking, dreaming and sleeping)

On the whole, the essays contained in this book deal mainly with personal philosophy and religious problems , and they show, with the exception of those of Prof Dasgupta and Prof Chatterji, that absolutism is in great favour in contemporary Indian thought This is an indication of the strong influence of religion on philosophy, which will continue to be an outstanding characteristic of the Hindu mind

The Structure and Development of the Fungi

By Dame H C I Gwynne Vaughan and Dr B Barnes Second edition. Pp xvi+449 (Cambridge At the University Press, 1937) 18s net

TEACHERS and students of botany and mycology will warmly welcome the second edition of this well known book During the decade which has elapsed since the book was first published, research on the fungi has been ardently pursued , much additional knowledge has therefore been incorporated in the present edition, illustrated by figures of the same excellence as characterized the book originally Among many new features one is glad to see the inclusion of a section on the interesting group of the Blastocladiales, an account of the recently discovered function of the spermatia of the rusts, and a much fuller discussion of the phenomena of heterothallism and variation in the fungi than was possible in 1927 Some new methods are described in the chapter on technique and the references to literature have, in general been brought up to date

As indicated by the title the book deals primarily with the morphology of the fungi and only in a subsidiary manner is their mode of life discussed In a few instances reference to the latter has not incorporated recent work for example, some authorities consider that the primary cause of larch canker is frost and not *Dasyscypha Willkommii*, and fresh light has been thrown on the parasitism of *Epichloe typhina* and *Armillaria mellea* It is now scarcely true to say that the Ustilaginales are obligate parasites, for several species have been cultivated on artificial media *Ustilago Carbo* treated as a single species, is really a complex of species with diverse life histories These however, are but minor imperfections in a book of generally supreme excellence In fact the authors have described the structure and development of the fungi so well that an urgent appeal can be made to them either to include a fuller account of the general biology of these organisms in the next edition or to write a companion volume on this theme

Physik fur Studierende an Technischen Hochschulen und Universitaten

Von Dr Paul Wessel Herausgegeben von Dr V Riederer von Paar Pp xii + 550 (Munchen Ernst Reinhardt, 1938) 4 90 gold marks

THIS text book of physics for engineers and technical college students is a kind of pocket edition of an intermediate course in physics with certain elaborations and unusual features While the fundamentals are surveyed, in an effective and extremely compact manner, in two main divisions of the work extending over some 350 pages in which special reference is made to X rays and crystal structure and to atomic physics, the whole of the foregoing material is later re surveyed in a more condensed fashion as a revision course occupying some 50 pages This is followed by another 50 pages containing a series of questions and answers, the latter usually taking the form of a reference to the appropriate page on which the relevant information necessary for a correct answer is to be found Finally are given a goodly collection of mathematical and physical tables, where in addition to much useful data normally required by engineers and physicists and to be expected in a book of this nature, are given tables such as those of the isotopes of xenon, the families of radioactive elements and the wave lengths of the K series of the X ray spectra of various elements, the usefulness of which is not obvious

The work is well illustrated and indexed, and should be most helpful to English speaking students who wish to acquire a knowledge of scientific German.

A Monograph on Veins

By Kenneth J Franklin Pp xvii+410 London Baillière Tindall and Cox 1937) *27s*

IF anyone supposes that little is known about veins his opinion will be altered when he reads this scholarly but interesting monograph which covers the whole literature from the sixth century B C to 1936 from the points of view of the anatomist embryologist pharmacologist histologist clinician historian and photographer—in fact from the point of view of the physiologist

Veins have been Dr Franklin s principal interest since 1924 and he has published many papers describing skilful work carried out with careful accuracy Fleisch and Gollwitzer Meier have simultaneously concentrated on the same problem Few people have known enough about veins to appreciate the significance of this work but Dr Franklin has now fitted the pieces together He was himself surprised at how well they fitted and many of his readers will share his emotion It must not be imagined however that the picture is complete for many fundamental problems are still a matter of controversy For example John Hunter suggested that the pulsations in arteries acted on veins like the movements of a piston in a pump forcing the blood past the valves This theory has been accepted by some and rejected by others, but the propulsive effect has never been demonstrated though compression of veins by the pulse has been observed by X rays in men and dogs

The subjects discussed include the blood depots the peculiar vascular anatomy of diving animals the effects of muscular contraction and respiration on the venous return the pharmacological and nervous control of veins venous pressure arterio venous anastomoses varicose veins and the history of intra venous injections and venesection

The book is attractively produced with excellent photographs diagrams and historical portraits About 1 200 references are given in the bibliography

The Annual Register

A Review of Public Events at Home and Abroad for the Year 1937 New Series Edited by Dr M Epstein Pp xiv +488 (London Longmans Green and Co Ltd 1938) 30*s* net

WITH unfailing punctuality this concise review of world history and achievement makes its appearance A calm review of the stormy year of 1937 can have been no easy task but it has been achieved without bias yet with enough spirit and vivacity to make it readable from beginning to end As usual British and foreign history each occupy about one third of the book Particular praise may be given to the survey of internal affairs in Great Britain and to the accounts of Germany and the Soviet Union Spain China Japan and the United States also occupy many pages The writer of the survey of the literature of the year comments on the deterioration in standards of human justice and the discouragement of free speech which he believes have tended to slacken creative effort Unfortunately it is impossible to deny this belief The survey of science however records advances in several directions although the condensation of the account no doubt on the grounds of space is almost excessive There are also the usual surveys of art drama law and finance Among the public documents printed in full are the Constitution of Ireland and the United States Neutrality Act The obituaries of the year give admirable biographies of eminent men and women of all countries

Théorie Cinétique des Liquids

1 Fluctuations en Densité *2* La propagation et la Diffusion de la Lumière Par Prof J Yvon (Actualités scientifique et industrielles Nos 542 and 543) Pp 133 together 18 francs each

THE author develops a theory of the propagation and diffusion of plane polarized light without change of wave length by a monatomic liquid for example argon the molecules of which are assumed to be spherical and isotropic The first part deals with the density distribution and the effect on it of gravity and thermal agitation the second with the dielectric constant refractive index and diffusion of such a liquid the statistical method of Gibbs being used throughout An expression for the ratio of the strength of the source of diffused light furnished by a volume of the liquid per unit intensity of the incident light (Rayleigh s ratio) is obtained which agrees satisfactorily with experimental results for benzene but not for water As neither is monatomic observations on monatomic liquids are required before attempts are made to extend the theory to complex molecules Each part contains nearly 100 references

The Statesman s Year Book

Statistical and Historical Annual of the States of the World for the Year 1938 Edited by Dr M Epstein Seventy fifth Annual Publication revised after Official Returns Pp xxvi + 1497 (London Macmillan and Co Ltd 1938) 20*s* net

THIS annual has effected a significant change this year The first part of the book is no longer entitled The British Empire but has become The British Commonwealth of Nations Within this embracing title comes first of all the British Empire including Great Britain and Northern Ireland the Colonies Protectorates, India and Burma and secondly the Dominions concluding with Ireland The remaining sections of the book have undergone no change in arrangement but the usual careful revision in detail Abyssinia and Austria linger in their alphabetical places but all effective and other changes in their Governments are noted The section on the States of Germany has disappeared As usual corrections and additions are made up to the end of March or even later Of the two coloured maps one illustrates the strategic position of Singapore and the second shows the distribution of steel production and associated ores, iron, manganese chromite etc , throughout the world

James Gregory (1638-1675)*

By Prof. H. W. Turnbull, F.R.S.

IN the early seventeenth century, two brothers, Alexander and David Anderson of Aberdeen, rose to mathematical distinction Alexander, who went to Paris as professor of mathematics, became the friend and expositor of Vieta, while David, commonly called 'Davie-do-a'-thing', became the Archimedes of Aberdeen, constructed the spire of St Nicholas Church, and removed 'Knock Maitland', a dangerous submerged rock, from the harbour by harnessing it to the tide His daughter Janet married the Rev John Gregory, of Drumoak on Deeside, twelve miles from Aberdeen, and thereafter for two hundred years their descendants occupied the chairs of either mathematics, medicine or philosophy in an unbroken sequence at Scottish universities, always with vitality and distinction

The greatest of this remarkable family was James, the third son of John and Janet Gregory, who gained renown for the invention of the reflecting telescope, but was also a mathematician whose genius is outstanding even among the giants of the age of Newton James was born in 1638, the year when Descartes gave analytical geometry to the world and Galileo his laws of motion , he died prematurely in 1675, of a sudden illness accompanied by blindness which befell him as he was observing the planet Jupiter in company with his students at Edinburgh He received his first lessons in mathematics from his mother , he eagerly mastered Euclid's 'Elements" given to him by his elder brother David at the age of thirteen or fourteen , he went to the Grammar School and later to Marischal College at Aberdeen, where he graduated

By the age of twenty-four years, James Gregory had written his "Optica Promota", which contains an elegant and geometrically accurate account of mirrors and lenses, beginning with the re-discovery of the sine law (of Snellius and Descartes), dealing with elliptical and hyperbolic surfaces and ending with a description of a reflecting telescope An astronomical appendix also suggests the importance of observing the transits of Venus and Mercury for calculating parallax In 1663, Gregory went to London and the book was published He met Collins and Hooke, who put him in touch with the celebrated optician Reive; Reive tried to make such a telescope, but the resulting mirrors were a failure and the attempt was abandoned. But Hooke, that prince of experimenters, persevered, and in February 1674 presented the first Gregorian telescope to the Royal Society, and the same form was universally employed in the eighteenth century

Gregory spent the next three years in Italy, chiefly at Padua, where the great Galileo had taught There Gregory printed, in 1667, his 'Vera Circuli et Hyperbolæ Quadratura", wherein he showed how to find the area of the sector of a conic by means of convergent polygons, and actually attempted to prove the transcendence of the ratios nowadays denoted by π and e (He considered π and also the number 2 3025850929940456 which is $\log_e 10$, this he calculated correctly to seventeen figures) The book lays the foundations of hyperbolic sines and cosines, as well as the concepts of convergence and algebraic invariance under transformations

In 1668, Gregory returned to England with a third book, the 'Geometriæ Pars Universalis", which gives a systematic *geometrical* account of the calculus, based on the work of Cavalieri and Fermat It contains the earliest proof of the fundamental theorem—that the method of tangents (differentiation) and of quadratures (integration) are converses of each other It also shows how to transform $\int y\,dx$ to $\int z\,dy$, where $z\,dy/dx = y$ This book profoundly influenced Barrow, who published his "Geometriæ Lectiones" in 1670

Gregory remained in London until the autumn of 1668 with Collins, who egged him on to solve the unproved theorems of the day As a result he produced a booklet, the "Exercitationes", containing a remarkable method of reversing a power series $f(x)$ in the form $x = \Sigma c_n f(x/2_n)$, together with rigid proof of Mercator's theorem on the expansion of $\log(1+x)$ By integrating sec x and tan x Gregory cleared up the mystery of the rumb spiral, explaining why Wright's "Nautical Tables" of 1599 actually presented a set of logarithms, of which the author was unaware

In 1668 Gregory was appointed first professor of mathematics in St Andrews, where he resided until 1674 Partly owing to a conflict with Huygens over the "Vera Quadratura" and partly through hearing of Newton's success in the "Analytics", Gregory never again published his mathematical work, beyond adding one short note to a vehement little book on the "New Art of Weighing Vanity", written by a colleague, William Sanders, a regent at St Leonard's College, St. Andrews , this book was directed against George Sinclair, a retired professor of natural philosophy at Glasgow, who had quarrelled with Sanders. The note contains the expansion of an elliptic integral in a doubly infinite series and solves the finite motion of a circular pendulum. In 1674 Gregory was appointed to the chair of mathematics in Edinburgh, which he only held for a year before he died. He married in 1669 Mary, daughter of George Jamesone the painter, and widow of Peter Burnet, of Aberdeen, and they had two daughters and a son, James, afterwards professor of physic in King's College, Aberdeen (d. 1731).

---

* Substance of a paper presented on Monday, July 4, 1938, at the Royal Society, Edinburgh, and also of an address on Tuesday, July 5, at the Tercentenary Graduation, University of St Andrews.

A long correspondence (1668–1675) between Gregory and Collins has happily been preserved. Gregory's letters were printed in Rigaud's "Correspondence of Scientific Men of the 17th Century". Collins's letters, which are now in the University Library at St. Andrews, have never yet been published, but the present tercentenary year affords an appropriate opportunity for doing so, particularly as they contain—on the blank spaces of the letters—some fifty mathematical notes of James Gregory in his own hand, revealing either the methods employed in such results as he sent to Collins by letter, or in still newer work which never saw the light. Careful scrutiny, begun in 1932, has unravelled their contents, and shows that Gregory actually anticipated Taylor, by forty-five years, in his famous expansion theorem, that Gregory could integrate $\sin^n \theta$, and had gone deeply into the theory of rational right-angled triangles and Diophantine quadratic equations. It is now possible to judge how slight was his mathematical contact with Newton; also how Barrow and Gregory influenced one another. It is noteworthy that Gregory probably never even heard of the name of Leibniz. These discoveries among the old letters go far to explain the fact that in his day Gregory was held to be second only to Newton.

Vaccination of Cattle against Foot-and-Mouth Disease

THE devastating epizootic of foot-and-mouth disease which has raged over Western and Central Europe amongst cattle, sheep and pigs since last autumn has by no means come to an end, though there have been some signs of local or temporary abatement in those areas first invaded in Holland, Belgium and parts of France and Germany. Sweden, Norway and Denmark have suffered little, and are always ready to stop early invasion by slaughter. In Great Britain there have been exceptionally severe and numerous outbreaks, but the number of farms affected and of animals infected or lost by slaughter has not approached that of the Continental calamity. On June 1 last, the number of farms infected in Germany was officially reported as 42,306.

Persistent research work in Germany has been carried out for forty years almost continuously, and since the Great War by Waldmann on the island of Riems; in France much valuable work was also done by Vallée at Alfort. In Great Britain research has been in progress since 1924, but though knowledge of the disease has increased, it has only been possible to increase the means of control in special circumstances and to reduce the spread of infection. Experimental stations have also been set up in recent years in Holland and Denmark.

The chief aim of investigation has been to find a method of protective vaccination, and many attempts have been made to devise a safe vaccine made from the virus, attenuated by biological, chemical or physical treatment, or made safe by the manner of its administration.

Inactivation of the virus by formalin has until recently appeared to be the most hopeful method, and has perhaps never been tried in the field with sufficient care and persistence. During the last few years, a technique of adsorption of virus with aluminium hydroxide has been very carefully worked out with great detail by Schmidt and his colleagues in Denmark on guinea pigs, and very promising results have been published. He attached great importance to the administration of the adsorbate-vaccine subcutaneously, for by other routes it was capable of producing infection. The results of vaccination given by Schmidt closely resemble those obtained with formalinized vaccine, but the adsorbate appears to be less safe and to give a somewhat higher degree of protection, as might be expected from a less completely inactivated virus. Waldmann maintains that Schmidt's vaccine is too dangerous, and he does not accept the suggestion that the active virus can only be released so slowly from the adsorbate as to be safe though still capable of giving active immunity.

A modification of Schmidt's vaccine has recently been used by Waldmann in Germany with additional safeguards to ensure its inability to produce the disease and spread infection. It was first tested on cattle at the Riems station with good results. The accessory chemical or physical means of attenuation devised by Waldmann have not yet been published, though an account of the vaccination of more than 40,000 cattle with this preparation has appeared in the *Berliner tierarztlicher Wochenschrift*, Nos. 22 and 24 (1938).

The initial difficulty in vaccination so as to prevent an invasion of the disease has always been that the vaccine must be prepared from active virus, and only relatively small quantities of virus can be obtained from one infected cow

The immense number of infected animals in Germany at the present time, and the high degree of organization in the collection of material in outbreaks in separated districts, and in the preparation of the vaccine from the virus, have enabled this relatively large trial to be made in that country The hope expressed that it will be possible to cultivate *in vitro* large quantities of suitable virus has so far not been realized The results of the campaign reported from the areas dealt with appear to be good Vaccine has been given to more than 40,000 cattle with apparently no spread of infection from the vaccinated animals It is claimed that almost 100 per cent of the vaccinated animals have developed immunity within fourteen days and some degree of resistance in five days There is also some evidence that the immunity lasted two to three months at least Sheep, goats and pigs were not vaccinated as they were considered much less susceptible than cattle, and few outbreaks in these animals are mentioned in the areas where cattle were vaccinated Three different groups of animals were vaccinated

The first group of 9,582 normal cattle were in an uninfected district and were isolated for ten days to test the inability of the vaccine to infect normal cattle The cattle were in thirty-three villages (950 farms) and were vaccinated between March 8 and April 9 No instances of the vaccine producing the disease were observed, only six cases of infection occurred, and there appeared to be good reason to attribute these to other sources The animals also presumably developed a good immunity, as they remained free from the disease in the neighbourhood of an advancing epizootic

The second group consisted of 19,486 normal cattle in districts where already a single outbreak had occurred, in this group, though a number of infections occurred in the first fortnight after vaccination, fresh cases then ceased and the animals appeared to have become immune

The third group of 11,608 cattle was in districts where several outbreaks had already occurred and many of the animals had received an anti-serum The number of cases after vaccination here was large, but fresh cases did not appear after the twelfth to fourteenth day, and this immunity was attributed to the vaccine The districts for vaccination were selected because they were in the line of advance of the epizootic It is stated that even eight days after vaccination the cases of disease appearing were fewer and less severe, and after fourteen days the immunity was almost complete

In this field experiment there were no exact 'controls', and the course which the epizootic would have taken in the absence of vaccination could be inferred only from the events in the early days after vaccination and records of its course in other unvaccinated farms, the latter details are not included in the published account It is possible that the synchronous and parallel outbreaks in other herds afforded sufficient 'controls', but the evidence has not appeared

The Scophony Television Receiver

By H. W. Lee, Scophony Laboratories

THE Scophony television receiver is an optico-mechanical system and possesses the advantages over the purely electric systems employing a cathode ray tube that (1) larger pictures are possible without great expense, (2) high voltages are not necessary—the voltage of a radio set is sufficient, (3) there is lower power consumption for a given picture size It is scarcely necessary to 'add that the Scophony receiver works on the B B C transmission

The essential parts of an optico-mechanical television receiver are (1) optical elements for producing an illuminated area on the screen, (2) means for moving the illuminated area over the screen; this is at present done by giving it two components of uniform motion in two directions at right angles, one horizontally and one vertically, (3) means for modulating the intensity of the illumination in accordance with that of corresponding areas of the picture to be reproduced. The modulated signals are received in the form of electro-magnetic waves and are converted into variations in voltage in an electrically tuned circuit, these have to be converted into variations in light intensity The difficulty of this conversion arises from the high frequency of the signals, which is 5×10^6 (The picture is divided up into approximately 500×400 elements and scanned 25 times a second) In sound recording, the highest frequency is of the order of 10^4 television has then an increase of 500 times It is thus easily understandable that mechanical light valves are out of the question nor is it possible to apply the electrical variations directly to a lighting circuit because a sufficiently brilliant source cannot be extinguished from its condition of maximum illumination in one five millionth of a second The Kerr effect was formerly employed and is still used in the telegraphic transmission of pictures but the light flux that the Kerr cell can handle is too small for high definition television (It has other disadvantages such as high capacity causing time lag)

The Scophony Light Control invented by J H Jeffree employs a cell which may be 10 cm × 2 cm in area and allowing ample light flux its action is based on the diffraction of light by compressional waves generated in liquid which act as a grating Electrodes connected to the electric circuit excited by the radio waves are attached to a quartz plate of which the thickness is such that the natural period of vibration under electric oscillations is 10 megacycles A parallel beam of light is sent through the cell and (in order to separate the diffracted from the undiffracted light) brought to a focus by means of a lens An opaque shield cuts off the light of zero order (undiffracted light) and the diffracted light (three orders of spectrum are used) passes to the screen The amplitude of the oscillation in the crystal and of the compressional waves produced in the liquid at any time is proportional to that of the electrical oscillations which in turn is proportional to the light received at the instant from the element of the picture which is being scanned As the supersonic wave travels along the cell it is followed by a rotating mirror of a mirror drum so that the small beam of diffracted light from it to the mirror is reflected in a fixed direction in space (compare the action of the heliostat mirror in following the sun s motion) A lens forms an image of the cell on the screen so that the amount of light reaching a point on the screen is proportional to that of the corresponding point on the picture but—and this explains the increased optical efficiency of this light control—the point is illuminated not for one five millionth of a second but for the time the wave takes to travel along the cell If we take the cell as 10 cm long this time since the average speed of the waves at the frequency specified is about 1 000 m per sec amounts to one thousandth of a second—a 500 fold increase

We have been considering the line scan' The number of traverses the illuminated area makes per picture is called the number of lines (the B B C standard is 405) and so the illuminated area which in one direction may be equal to the width of the picture must be limited in a perpendicular direction to a line width or 1/405 part of the picture height This means that the image of the light cell on the screen must be compressed to do this cylindrical lenses are required Moreover to reduce the length of the scanning drum so as to keep its inertia small in order that the power required to drive and synchronize it may not be excessive the light beam is still further compressed in this direction This is the principal of the split focus invented by G W Walton[2] it is only by this reduction in size that it is possible to drive and synchronize the high speed drum at 30 000 r p m The drum is driven by an asynchronous motor and synchronized by means of a phonic wheel to which the synchronizing pulses of the transmission are applied At the high speed used glass would fly to pieces so stainless steel is used which metal is necessary in order to obtain optically polished mirror faces The amount of steel is kept at a minimum and the drum is in fact a steel annulus with an aluminium core The inertia can thus be brought down to 137 gram cm^2 The slow speed drum to provide the scanning in the other direction has to change the picture (or frame) 50 times a second and moves only 1/202 5 times as fast as the high speed drum for the same number of faces and there does not arise the same need to reduce size

Fig 1 shows the lay out of the system but in order to show the optical arrangement conventional sections made in two planes at right angles through the axis are shown (Fig 2) Here the scanners are only indicated and for the sake of clearness the rays are shown undeviated by reflection at the scanners

The lenses B_1 and C have a two fold function Inasmuch as C images the supersonic waves in the cell on to the screen B_1 may be regarded as a field lens to C reducing its size On the other hand the lenses B_1 and C have to form a well defined image (of the light source) on the opaque shield and furthermore they have to fulfil a condition which is peculiar to the Scophony optical system A ray parallel to the axis impinging on the supersonic wave field at P at a distance h from the axis is brought to a focus at the shield at an angle θ to the axis Now P travels with uniform linear speed along the cell and the mirror drum rotates with uniform angular velocity it is therefore seen that the condition $h/\theta =$ constant must be fulfilled[3] (Compare the aplanatic or sine condition $h/\sin\theta =$ constant)

The above condition being satisfied the following relationship must hold

Equivalent focal length of B_1 and C is equal to the ratio of velocity of the supersonic waves to rotation speed of scanner Putting the velocity of the supersonic waves at 1 000 m sec = 10^5 cm sec and speed of rotation of drum at 500 r p m we get equivalent focal length = $50/\pi$ = 16 cm approximately Now as there are 405 lines to the picture and 25 pictures per second (or 50 pictures of 202 5 lines in the interlaced system) there are 10 125 line changes per second Therefore the supersonic waves must travel along the cell in 1/10 125 sec so that the size of the cell is

$$\frac{100\ 000}{10\ 125} = 10 \text{ cm}$$

approximately

The aperture ratio of the two lenses B and C is therefore $\frac{10}{16}$ or 1 1 6

For a cell 10 cm long holding 500 elements of the picture (an element being equal to the line width) each element occupies a space 0 02 cm The wave length of the supersonic waves is $\frac{10}{10}$ (frequency 10) 10 cm so that an element of the picture is carried by two complete waves Nomoto has shown that a width of two waves produces the diffraction phenomena

The equivalent focal length of B_2 and C being 16 cm and the angle of diffraction being equal to (wave length of light) (wave length of supersonic waves) = 0 55 × 10^{-4} 10^{-2} = 0 0055 radians for light for which the eye has maximum sensitivity the centre of the first order diffraction spectrum is displaced 16 × 0 0055 = 0 09 cm from the axis the centre of the second order diffraction spectrum is displaced 32 × 0 0055 = 0 18 cm from the axis and that of the third order spectrum 48 × 0 0055 = 0 27 cm from the axis It has been found experimentally that approximately 45 per cent of the light is diverted into the first order (at maximum modulation) 37 per cent into the second and 8 per cent into the third (with negligible amounts in the higher orders so that about 10 per cent is lost) Now the amount of light in the zero order is directly proportional to the area of the zero order that is the image of the light source formed by undiffracted light but the amount of light in the diffracted spectra is not proportional to the area unless this is very small because as the area is increased some of the diffracted light is cut off by the opaque shield, which must be equal in width to the zero order It can be shown on the basis of the above measurements that the amount of light increases rapidly as the size of zero order is increased to 1 8 mm

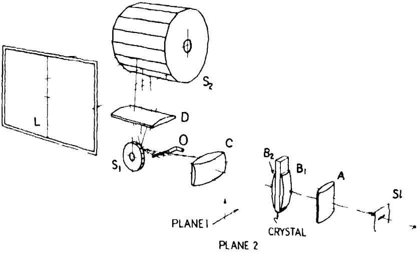

Fig 1

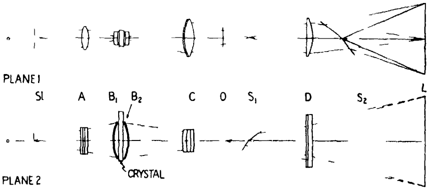

Fig 2

Sl is an illuminated slit

A is a cylindrical condenser focusing the slit in the cell in Plane 1

B₁ collimates the light from Sl to pass through the cell as a parallel beam

B₂ focuses it with the aid of C on the opaque shield O

C forms an image of the cell on the screen L in Plane 2 and an image of the light source on the scanner S₁ in Plane 1

S₁ and S₂ are the two scanners

D forms the line image

less rapidly for an increase to 2 6 mm and thereafter very slowly These calculations cannot be very accurate as no account is taken of light of different wave-lengths, but experiment is in agreement that a size of 2 5–3 mm gives optimum results It is preferable to interchange slit and shield, placing the shield in front of the light source and the slit in front of the scanner[4], this arrangement gives a solid beam of light, instead of one having a hollow centre, taking up less room on the scanner The diffracted light from this source can be dealt with very efficiently by a scanner of 5 cm diameter

A larger light source could be used by increasing the angle of diffraction by reducing the wave-length of the supersonic waves To this there are several objections shorter waves are more rapidly absorbed by the liquid (Nomoto states that no diffraction spectra can be obtained at frequencies of 30 megacycles, so that no great increase of frequency is possible), a larger light source would require a larger scanner, which would increase the difficulties of synchronization and driving, and finally, more power would be required to 'drive' the crystal (this is at present about 6 watts)

A rough idea of the accuracy required in the scanner can be obtained by considering that in the Scophony system a picture line of 500 elements is scanned by a rotation of 18° by the scanner One element therefore corresponds to about 2 minutes of arc Each surface of the scanner must therefore be placed accurately to a fraction of a minute of arc

The present Scophony receivers, although operating by no means at the limit of optical efficiency, give the satisfactory screen brightness of 15 lux The home receiver gives a picture 2 ft wide, using a mercury vapour lamp The public hall receiver gives a picture 6 ft wide, using a standard cinema arc consuming 100 amperes

Obituary Notices

Prof. W. A. Bone, F.R.S.

THE death of Prof William Arthur Bone on June 11 has removed from the field of fuel science one of its most prominent figures and distinguished research workers So ended a career which has been remarkably effective in linking up achievements in the realm of theory with their applications to industrial progress over a long term of years.

Bone left the Friends' School at Ackworth and the Leys School, Cambridge, for chemical training at the University of Manchester at a time when a study of the properties of gases in explosion and combustion was already coming into prominence there, thanks very largely to the work of H B Dixon, and this course of training at home was supplemented by a period abroad with Victor Meyer His promise as a student was indicated by the award of the Mercer Scholarship, Leblanc Medal and the Berkeley Fellowship at Manchester, and the Ph D at Heidelberg In 1896, he became head of the Chemical Department at Battersea Polytechnic for two years, and then returned to Manchester as lecturer in fuel and metallurgy

In the following years he began to make his mark as an investigator in the subject which, in one form or other, was to engage his attention during the whole of his working life It was the work Bone did at that time which was largely responsible for a revision of the current ideas respecting the mechanism of the combustion of hydrocarbons and similar phenomena The notion of the preferential combustion of carbon on one hand or hydrogen on the other in these compounds, which had been the subject of much discussion and many claims, gave place in the light of his researches to the more rational hydroxylation theory, in which the preliminary association of the oxygen with the hydrocarbon was not simply assumed to be probable, but demonstrated experimentally to occur The successful outcome of this work was brought about by a combination of clear thinking and first class experimental technique, which was to be a distinguishing mark of Bone's work throughout life as an investigator

Meanwhile, at the sister University of Leeds, Prof Arthur Smithells had also turned his attention to combustion phenomena and study of flame, and in 1907 he had so far impressed the Council at Leeds with the importance of fuel as a proper subject of university study, that the first chair in the subject was founded there, and Bone was invited to become its first occupant During this time, Bone had been turning his attention to other phenomena of gaseous combustion which depended on the enormous influence exercised by hot solid surfaces on the rate of combustion of gaseous mixtures in contact with them This 'surface-combustion' lent itself to striking experimental demonstrations and was made the subject of various industrial applications which, in one form or another, have been taking their place in gas-burning apparatus from that time onwards The Bonecourt boiler is perhaps the best known example in which a very high rate of combustion and evaporation are obtained by burning a gas-air mixture in close contact with a solid packing of the boiler tubes.

In this part of his work Bone collaborated with McCourt and with the Leeds firm of Wilson and Mathieson.

In 1910 the association of the Fuel Department at the University of Leeds and the gas industry was cemented by the endowment of a chair of coal gas and fuel industries as a memorial to the recently deceased leader of the gas industry, Sir George Livesey, and Bone was made the first Livesey professor, a post which he occupied until 1912. As Livesey professor, apart from his more personal research work, he was occupied with that of a Joint Gas Heating Research Committee of the University of Leeds and the Institution of Gas Engineers which carried out the first systematic investigation of the radiant efficiency of the gas fire. It may be mentioned here that Bone's interest in fuel matters had a wide range, and that partly no doubt on account of a family connexion with the iron works at Skinningrove he was always specially interested in the fuel problems of the iron and steel industry. That was brought into prominence later in his life by an investigation which he carried out on the mechanism of iron ore reduction in the blast furnace, but as early as 1907 the same interest was manifested by the reading of a paper before the Iron and Steel Institute entitled "An Investigation on the Use of Steam in Gas Producer Practice". In this work, his collaborator was R V Wheeler, who later became professor of fuel at Sheffield, and it was carried out at the works of Messrs Monks Hall and Company of Warrington. It was not original in the sense of disclosing any new chemical phenomena but was a systematic and thorough examination of a prominent feature of gas producer practice on which very necessary information had been lacking, and its results have been freely utilized since that time.

In 1912, Bone transferred the scene of his activities to London. The *Imperial College* had awakened to the importance of the study of fuel, and invited Prof Bone to take over that and allied subjects in London. The headship of that Department was his official position for the rest of his life. The teaching there was post graduate, and he was enabled to devote most of his energies to the work of research. So early as 1905 he had been elected a fellow of the Royal Society, and in its *Transactions* and *Proceedings* were published most of his contributions to science.

The most striking development in Bone's work on gases was an extension of the study of the phenomena accompanying their oxidation and decomposition under high pressures in ranges including and far surpassing those used in internal combustion engines. In the elucidation of these phenomena, the principles which he accepted and applied were those which had already served him well, and he was very unwilling to depart from them in any way.

Another branch of work which occupied Bone in later years was the investigation of the constitution of coal and other natural fuels by pressure extraction with benzene and oxidation with permanganate. This work proved fruitful in his hands, and was supported by the Department of Scientific and Industrial Research. The distinguishing feature of this investigation, in my opinion, was the thoroughness of the survey undertaken, particularly on the quantitative side. By the establishment of carbon balances Bone was able to show that the products of permanganate oxidation not only contained such substances as benzene carboxylic acids, but also that these were derived in such quantities from even the less matured coals as made it legitimate to conclude that coal was essentially benzenoid in constitution. The value of this and his other research work was so far appreciated that after his retirement from the chair at the Imperial College on reaching the age limit in 1936 arrangements were made for placing at his disposal a laboratory and assistants for the continuation of his work.

Apart from his many published papers and the numerous lectures which he delivered to representative gatherings, Prof Bone wrote several books on the subjects in which he was specially interested, including "Coal and its Scientific Uses", "Gaseous Combustion at High Pressures", "Coal, its Constitution and Uses", and "Flame and Combustion in Gases". The last named work was written in collaboration with his assistant Dr D T A Townend, and in the last letter which I received from him, Bone expressed his gratification in learning that Townend had just been appointed to the Livesey professorship, of which he had been the first holder. The number of scientific and technical societies, national and other committees, with which Bone had been connected gives some indication of the reputation which he had established, but it is probably as a research worker that he will be best remembered.

JOHN W COBB

Mr J G Hides

THE death is reported of Mr J G Hides, explorer in Papua, which took place in Sydney at the age of thirty two years. Mr Hides was born at Port Moresby, Papua, and educated in Australia. He joined the Papuan Government service in 1925, and served successively as patrol officer and assistant resident magistrate. He showed an exceptional understanding of native mentality. In 1935 he carried out a patrol lasting eight months, in which he discovered in previously unexplored plateau country an unknown, and as he maintained, new race of light skinned people. The origin and identity of these people, whose culture displayed a number of features new to Papua, have been the subject of much discussion. Hides, who resigned from the service to take up gold prospecting in 1936, described his experiences and explorations in "Through Wildest Papua" (1935) and "Papuan Wonderland".

WE regret to announce the following deaths:

Dr A Galt, keeper of the Technological Department, Royal Scottish Museum, Edinburgh, in 1901–20, on June 26, aged eighty three years.

Mr W M Mordey, known for his work on the development of electro magnetic machinery and on alternating current magnetism, on July 1, aged eighty two years.

News and Views

Royal Society of Edinburgh Awards

The following have been elected honorary fellows of the Royal Society of Edinburgh *British* Sir Thomas Lewis, physician in charge of the Department of Clinical Research, University College Hospital, London, Prof G I Taylor, Yarrow research professor of the Royal Society, fellow of Trinity College, Cambridge *Foreign* Prof F Enriques, professor of mathematics, Royal University, Rome, Dr H N Russell, chairman of the Department of Astronomy and director of the Observatory, Princeton University, U S A, and Karl Freiherr von Tubeuf, professor of botany, University of Munich The joint committee of representatives of the Royal Society of Edinburgh, the Royal Physical Society and the Royal Scottish Geographical Society has awarded the Bruce Memorial Prize (1938) to Mr Alexander R Glen for his work in Spitsbergen, including survey in New Friesland and the completion of the map of North East Land The Council of the Royal Society of Edinburgh has awarded the David Anderson Berry Prize (1938) to Miss Mary A C Cowell, of the Holt Radium Institute, Manchester for her essay entitled 'An Investigation into some of the Factors affecting the Response of Human Skin and Human Skin Tumours to Radiation" The portrait of the president of the Society, Sir D'Arcy Thompson, by Mr David S Ewart, was presented by Prof F A E Crew, on behalf of the subscribers, at the meeting held on July 4

Tercentenary of James Gregory

The tercentenary celebrations of the birth of James Gregory began at the Royal Society, Edinburgh, on Monday, July 4, when papers by Profs H W Turnbull, F Enriques, M Dehn, E Hellinger and Dr O Prag were presented on the mathematical work of Gregory On Tuesday, July 5, a special graduation at the University of St Andrews was held in the Upper Library Hall, where Gregory had worked and made astronomical observations Honorary degrees were conferred on Profs G D Birkhoff of Harvard, A W Conway of University College, Dublin, O Neugebauer of Copenhagen, R Weitzenböck of Amsterdam, and (*in absentia*) V Volterra of Rome Addresses were received from the Royal Societies of London and Edinburgh, the London Mathematical Society, the Edinburgh Mathematical Society, and the Universities of Edinburgh, Cambridge, Paris, and from others An exhibition of books and scientific instruments associated with James Gregory was arranged in the Parliament Hall, Library Buildings, South Street, St Andrews

Prof. Sigmund Freud, For. Mem. R.S.

Among the distinguished scientific men of science who have left Vienna since the *Anschluss* is Prof Sigmund Freud, who has taken refuge in London Prof Freud celebrated his eighty second birthday on May 6 last His name will always be associated with the development of psycho analysis, and the significance of his contributions to psychology was acknowledged by his election in 1936 to foreign membership of the Royal Society, but Prof Freud had not hitherto been able to sign the roll of membership Although now resident in London Prof Freud was prevented by infirmity from attending the Society's rooms for this purpose and although the charter book is rarely removed from Burlington House except when it is taken to Buckingham Palace for the signature of the King as patron of the Society, it was decided to extend the privilege to Prof Freud Accordingly on June 23 Sir Albert Seward, foreign secretary and Prof A V Hill one of the secretaries accompanied Mr J D Griffith Davies, who as assistant secretary has custody of the charter book, to Prof Freud's residence, where the roll was duly signed by Prof Freud in the presence of his daughter, Dr Anna Freud, and Princess Marie of Greece, who was a pupil of his and received him when he left Austria On behalf of the Royal Society Sir Albert Seward presented to Prof Freud an inscribed copy of a facsimile of the Society's charter book

University of Birmingham. Physics Department

In April last the Council of the University of Birmingham, in considering a request from Prof M L Oliphant for an extension of the Physics Department, regretted that the demands made by the New Medical School would make such an extension impossible unless some private benefactor came forward to provide the necessary money At the meeting of the Council on June 29, it was announced that Lord Nuffield has offered to give the necessary amount of £60,000 Of this, a sum of £40,000 is to be used for the building, the remainder being reserved for equipment and maintenance and for the foundation of a research scholarship The plans for the new block provide for a professor's room and secretary's office, a staff room and library The central part is a large and lofty research hall for high-voltage work, this being flanked by eight small research rooms, each about 16 ft by 14 ft There are to be also a machine room and workshop, two dark rooms, and a basement room for high energy X ray work The general design of the laboratory is such as to lend itself to modification to provide for new developments which may from time to time become desirable The provision thus made for research will enable the existing physics block (with slight alteration) to be used for teaching purposes for which it was originally intended, and the unsightly temporary huts which since the Great War have been used as an extension of the Department will disappear

Birmingham Hospitals Centre

THE annual degree congregation at the University of Birmingham on July 2 marked the completion of the new medical school and the Birmingham Hospitals Centre by the conferment of honorary degrees on three laymen whose benefactions and services have been outstanding Sir Bertram Ford Viscount Nuffield and Mr Harry Vincent and three representatives of the medical profession Dr Robert Hutchison Sir Edward Mellanby and Sir Cuthbert Wallace At a luncheon afterwards the Guild of Graduates entertained the honorary graduates The chancellor, Viscount Cecil in proposing the toast of the new graduates referring to Lord Nuffield said that he was the successor of a very long line of splendid citizens They knew he stood for progress not only physically but also intellectually and morally When he made his splendid gifts he considered most carefully how they would be for the greatest advantage of the people he was anxious to benefit In the case of his gift to our department of Physics I think he felt that he was not only helping the University of Birmingham or the science of physics but indirectly in a most important degree giving assistance to the industry and intellectual advance of the whole country

DR ROBERT HUTCHISON congratulated the City and the University on the great work that had been carried out in forming the Hospitals Centre and expressed his belief that the example set by Birmingham in the concentration of medical resources in one quarter will be widely followed in other cities Sir Edward Mellanby said that the fight against disease has as its limiting factor lack of knowledge The present year has been a particularly good one from the point of view of discovery One of the greatest discoveries of the time has come from a Birmingham hospital Dudley Road namely the curative properties of the new drug M and B 693, which gives us considerable control over that terrible disease pneumonia The greatest part of research is the prevention of disease This is going on side by side with these other discoveries This other type of work the clearing out of disease, is becoming more and more powerful and I have no hesitation in saying that in fifty years your great hospital here will be put to other uses than it is to day It may, of course be full of motor accidents, or it may be full of very old people whiling away their last years of life in peace and happiness, or it may be occupied by the University for ordinary teaching At any rate it is going to be quite different, because the rate of progress is so rapid

National Museum for Southern Rhodesia

IT is reported that a national museum for Southern Rhodesia is to be instituted in the neighbourhood of the Zimbabwe ruins The trustees of the Southern Rhodesia Sweepstake Lotteries are to be asked to bear the cost of the building, but in the event of their being unable to provide the amount required, the sum necessary will be raised by the Government from its funds It is to be presumed from the location of the site that the museum though general in character as a national museum should be, will devote special attention to the antiquities of the adjacent Zimbabwe area and the culture of its native inhabitants past and present in which the Governments of South Africa have already evinced their interest by the assistance they have given to the archæological investigations undertaken by the joint universities committee for archæological research Although the situation of the museum may seem somewhat remote from any academic centre, this will scarcely prove a deterrent to the serious student who will appreciate the advantage of studying the culture of the Zimbabwe in its natural setting, more especially if it should prove possible to get together a really representative selection of the antiquities which have been found in the ruins from time to time The proximity of the museum to the Victoria Falls as well as to the ruins, should ensure that it does not suffer from lack of visitors As an illustration of the most remarkable feature in South Africa s cultural history such a collection should have the highest educational value

Prehistoric Research in Great Britain

THE Prehistoric Society (formerly the Prehistoric Society of East Anglia), has recently established a research fund with the object of undertaking the excavation of a series of key sites in Britain in order to develop our knowledge of the prehistory of the country Of the competence of the Society to undertake the direction and administration of such a fund there can be no question Its membership of seven hundred includes most of those prominent in the study of prehistoric archæology both in Great Britain and abroad, and among them are those who have been mainly responsible for recent rapid advances in our systematized knowledge of the mesolithic neolithic and iron age periods in Britain The advantages which will accrue from a research fund under the control of the Society are patent The facility for systematic planning of research, combined with flexibility in the application of effort both of man power and of financial resources, will make it possible to add effectively to the sum of organized knowledge in those periods and departments of British prehistory where it may be needed most from time to time A beginning is to be made in this season, when it is proposed to excavate an iron age village site near Britford, one mile south of Salisbury Cathedral This site is believed to belong to the earlier part of the period 500-100 B C The village enclosure was dug out of the chalk by its inhabitants and its form is known in some detail but only from photographs taken at a height of 2 000 ft in air survey, which revealed the existence of the site The object of the excavation will not be to lay bare the site as such, so much as to throw light on the mode of life and organization of a settlement of small farmers and stock raisers of the period The Society appeals for contributions to the research fund, which should be addressed to the Honorary Secretary, Mr C W Phillips, Selwyn College, Cambridge

Flint Implements of the Bronze Age

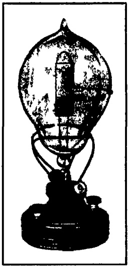
WHAT would appear to be a remarkable collection of flint implements of Bronze Age date unusually numerous for the period is reported (*The Times* June 28) to have been found on Lightlands Farm belonging to Mr George Lawrence of Frant Sussex It includes arrow heads tanged and barbed scrapers knives and flakes Apparently the implements belong to a pygmy flint industry The site is half a mile north east of the camp of Saxonbury It is on clay soil which has been ploughed for orchards The flints in consequence have been widely scattered It is pointed out that such sites are not common in the mid Weald to which the raw flint had to be carried either sixteen miles from the North Downs or eighteen miles from the South Downs Pygmy implements are more commonly found on the sandy sites fringing the Weald

The Attempt on Mount Everest

ONCE more the attempt to reach the summit of Mount Everest has failed *The Times* announces that Captain Oliver a member of the expedition has returned to Kalimpong and that the other members may shortly be expected there This year's party was a small one, but included men of great experience Mr H W Tilman the leader Mr N E Odell Captain P R Oliver Mr E E Shipton Mr F S Smythe and Dr C B Warren had all had experience on Mount Everest and elsewhere and Mr P Lloyd had distinguished himself on Nanda Devi A message from Mr Tilman to *The Times* confirms the news that the attempt has been abandoned for this year Some details are given Camp IV on the North Col was reached on May 26 but owing to bad conditions was abandoned five days later It was reoccupied on June 5 and on the following day Camp V at 25 300 ft was established Conditions were not promising although the weather was good at the time There was an exceptionally early monsoon with heavy snowfalls Avalanches were unusually numerous and several times endangered the expedition On June 8 Messrs Shipton and Smythe established Camp VI at 27 000 ft where they were joined by Messrs Tilman and Lloyd but beyond 27 300 ft the snow made progress impossible and the attempt was abandoned Two of the porters are seriously ill but the rest of the party is well

The First Radio Valve

SIR FELIX POLE recently made a presentation to Mr Charles Corbett who has completed fifty years unbroken service with the Edison Swan Electrical Co, Ltd Sir Felix pointed out that the company is the oldest electric lamp concern in Great Britain, and is the Company to whom Sir Ambrose Fleming was consultant when he produced the first radio valve In 1878 Sir Joseph Swan exhibited at Newcastle on Tyne the first electric lamp, and in 1881 formed the Swan Electric Light Co, Ltd, to manufacture and market electric lamps Two years later the names of Thomas Alva Edison and Joseph Swan were coupled by the amalgamation of their interests and patents in the formation of the Edison and Swan United Electric Light Co Ltd The factory became established at Ponders End In 1916 the Company's name was changed to the Edison Swan Electric Co Ltd About the time of the amalgamation Edison noted the irregular blackening of the inside of the lamp bulb during life Later this Edison effect was investigated in the laboratory by Sir Ambrose Fleming (then Prof J A Fleming) and a number of special carbon filament lamps were made for him for experimental purposes The result was in 1904 the Fleming thermionic valve Although this valve was no more than a simple carbon lamp of the period with a metal plate placed between the legs of a hairpin shaped filament it could detect wireless signals without the disadvantages common to the old coherers and other mechanical detectors Much remained to be done before the valve could be brought to that stage of comparative efficiency which was reached with the advent of broadcasting but something of the physics of the valve had been learned



University of London Observatory

ON July 1 in spite of a severe thunderstorm during which the roof of Mr Will Hay's house was set on fire by lightning, one hundred and sixty people attended the opening, by the Astronomer Royal of the new building of the University of London Observatory at Mill Hill in which the 24 in Radcliffe photographic refractor from Oxford and a library have been installed The Astronomer Royal was introduced to the guests (among whom were the Mayor and Mayoress of Hendon) in a short speech by Sir Frank Dyson chairman of the University Observatory Committee of Management, and gave an account of some of the circumstances which led to the founding of the Observatory in 1929 This had been largely due, he said, to the enthusiasm of the late Prof L N G Filon, who was made honorary director, and to Mr C C L Gregory, who was given the title of Wilson Observer Mention was made of the Wilson 24 in reflecting telescope which was presented to the University by Mr J G Wilson, and also of the gift by Mr. Fry of a smaller instrument, an 8 in. refractor by Cooke. The Astronomer Royal described the Radcliffe telescope as a sister telescope to the one now being used at Greenwich for parallax determinations, and hoped that much useful work along similar lines would be done in the future at Mill Hill, in keeping with the past traditions of the Radcliffe Observatory. The Radcliffe Observatory has now been removed to Pretoria, where the largest telescope in the southern hemisphere is being erected. The Vice-Chancellor, Sir Robert Pickard, thanked the Astronomer Royal on behalf of the University for performing the opening ceremony.

Museums and Rural Life

IN supporting the appeal for a further £5,000 for the endowment fund which was launched at the jubilee celebrations of the Haslemere Educational Museum, Dr. John Ramsbottom, president of the Linnean Society, stressed the great importance of teaching people of all classes how best to spend their leisure. The Haslemere Museum, he said, is worthy of unreserved praise, for it is part of the communal life of the district. Children and adults bring specimens of all kinds to the Museum for identification and are assured of receiving information, whether it be a matter of local history or natural history. He also referred to the magnificent display of British wild flowers with their names and such information as is sure to appeal, that is maintained in the Museum throughout the year. Lord Winterton suggested that research into the origin of the old wage-earning families in the neighbourhood of Haslemere would prove most interesting, for many of them are descended from migrants from France or Flanders in the fourteenth and fifteenth centuries. During that time there was a big trade between the Sussex and Hampshire ports with France and considerable migration between the two countries; also large numbers of workers came over for the extensive glass industry then existing in the south of England. In those days when anyone made any money it was put into land, and many of the place names—such as those of the woods, fields and so on in the neighbourhood—give indications of the names of the worker immigrants, some of them also being of Saxon origin.

Linnæus in England

THE Year Book of the Swedish Linnean Society for 1938 (Svenska Linné Sällskapets Årsskrift, Årg. 21) opens with a dedication to the Linnean Society of London on the occasion of its sesquicentenary, in which the elder Society is greeted as "chirographorum Caroli Linnaei pia conservatrix". The volume contains a long account, illustrated by photographs and drawings, of Linnæus's house in the old Botanical Gardens at Uppsala and of the way in which it has now been skilfully restored as nearly as possible to the state in which it was when Linnæus lived in it. Of the other articles one, by the editor, Mr. A. Hj. Uggla, is of special interest to readers in Great Britain, since it deals with two recently discovered documents bearing on Linnæus's connexion with England. One is a draft of a letter intended for, and perhaps actually sent to, Dillenius at Oxford in 1733, when Linnæus was twenty-five years old, and shortly after his expedition to Lapland. It is written in Latin and ends by expressing the hope that he might one day meet Dillenius. This hope was fulfilled when Linnæus visited Oxford three years later. The other document is a letter written in August 1735 by J. F. Gronovius in Leyden to Philip Miller, superintendent of the Apothecaries' Garden at Chelsea. It is written in English and states that Linnæus, then in Leyden, "hath a mind to make a step over to England to be acquainted with you. I am sure you will be pleased with his company but it will bee troublesome for him as only speaking his own Language and Latin however I think the Swedish minister at London can procure him an interpreter".

Experimental Fire-Walks

A REPORT by Dr. G. Burniston Brown on three experimental fire-walks has recently been issued ("A Report on Three Experimental Fire-Walks by Ahmed Hussain and others". By Dr. G. Burniston Brown. Bull. 4, University of London Council for Psychical Investigation, 19 Berkeley Street, Mayfair, London, W.1. 1s. net). The experiments were made at Carshalton, where Kuda Bux had also been tested (see NATURE, 136, 468, 521; 1935) and at the Alexandra Palace. The accompanying table shows a comparison of the most successful attempts made by Ahmed Hussain, R. Adcock and Kuda Bux.

	Weight	Distance walked	Surface temp. (°C.)	No. of steps	Time	Minimum mean time of contact per step
Hussain	128 lb.	12 ft.	800	4	1.6 s.	0.40
Adcock	160	1	800	3	1.8	0.60
Kuda Bux	1[illegible]	11	430	4	2.2	0.[illegible]5

The results of the experiment showed that the fire-walk is not a trick but is performed in the normal manner with bare and chemically untreated feet. Moisture on the feet was shown to be a disadvantage, since it may cause hot particles to adhere to the skin and thus cause blisters. The sudden formation of an insulating cushion of vapour between the foot and the hot embers does not occur and no abnormal degree of callosity of the feet is required.

The "Invisible College", 1645–1662

IN the Moravian literary publication, *Miscellanea*, Dr. R. F. Young recently gave an account of the "Invisible College" which preceded the foundation of the Royal Society in 1662. The term was used to describe the periodical meetings of men of science at either London or Oxford, and Dr. Young points out that the contemporary meaning may have been derived in four possible ways. In the first place, it may be an Italian *concetto* adopted directly by Boyle from the name of a literary academy at Cremona. It may have been borrowed from the contemporary critics and opponents of the "invisible" Rosicrucians, such as J. V. Andreae (1586–1654). A third view is that it was a reminiscence of an elaborate play on the word invisible contained in Shirley's comedy The Bird in a Cage (1633) The last possibility, towards which the author leans is that it was a title devised by Theodore Haak to contain an implicit allusion to Comenius's plan of an international pansophic college for scientific research to be erected in London This plan was much to the fore during Comenius's visit to England in 1641–42 and the scheme was set out in detail in his manuscript treatise, Via Lucis (1642) Haak was a German from the Palatinate who had been one of the principal supporters of the plan to establish a scientific academy in London He regarded the informal scientific meetings as the nucleus of a future State college of science and is likely to have used the expression Invisible College in conversation with Boyle and others The Philosophical College was thus the Invisible College until it definitely became the Royal Society

Medicine and Eugenics

THE Galton Lecture to the Eugenics Society by Prof John A Ryle on medicine and eugenics is printed in the *Eugenics Review* 30 No 1 In a carefully considered address it is pointed out that the eugenic movement needs the fuller support of the medical profession and that this can only be given when medical men receive a fuller training in human genetics than is now the case The family doctor is now rarely prepared even if asked to give advice connected with eugenic prognosis, although men and women are increasingly prepared to discuss such matters Practising physicians should be able to keep pedigree records of their patients who show mental and physical defects Medical education should be altered so as to lay greater stress on animal and human genetics in place of some of the routine zoology and the more specialized biochemistry and biophysics The constitutional variations which abound should be the subject of closer genetic study Several chairs of human genetics should be instituted and associated with them should be research centres concerned with morbid inheritance in man Wider contacts of the Eugenics Society with medical societies throughout the country would be helpful The foundation of a National Council is advocated embodying an alliance between medicine, eugenics and sociology and having appropriate contacts with the Ministries of Health, Agriculture and Labour The preservation of health as a primary function with the treatment of disease as a secondary function should become the new ideal

Forestry in Nyasaland

PERHAPS the most important information contained in the annual report of the Forestry Department for the Nyasaland Protectorate (for the year ending December 31, 1936 Govt Printer, Zomba, Nyasaland, 1937) are the remarks on soil erosion and the investigation work now being undertaken in this, considered to be one of the greatest dangers facing Africa as a whole Extensive areas were examined with particular regard to overcrowding and to cultivation on steep hill slopes in parts of the southern province On the subject of forest policy it is stated that provision is to be made for the demarcation, protection and management of selected forests and woodlands by native authorities, where the objects of conservation are comparatively local These local Government forests will be supplementary to the State forests but they will in no way supersede the village forests which are managed by the village headmen solely in the interests of village needs There will thus be three types of demarcated forests in the future each managed by its own authority One of the chief dangers in many parts, owing to the improvident habits of the people is erosion Provided that each type of forest reservation may be made to serve as a protective agent against this evil, the steps now being taken appear to meet existing problems

Science and Horticulture

VOL 6 of *Scientific Horticulture* (260 pp 1938, from the Editor R I Pearl S E Agric Coll Wye Kent 4*s* net 4*s* 6*d* post paid) the journal of the Horticultural Education Association contains a very useful series of reviews upon the science and practice of horticulture A suitable introduction is provided by Mr F A Secrett who writes upon the enterprise and skill requisite for successful market gardening and the need for evolving schemes to assist Nature The article is the text of an evening address delivered at the University of Reading during the Association's revision course in horticulture in September 1937 Papers read at this course are published in the present volume they minister chiefly to the needs of flower growers with emphasis upon carnations, roses pot plants and chrysanthemums both early and late There are further papers on genetics in relation to horticulture the nature of inheritance of flower colour and on photoperiodism Papers contributed specially to the volume include a review of recent Dutch research upon the growth and flowering of tulips and daffodils by Miss O N Purvis upon hormones (M Thomas) boron deficiency (A W Greenhill) chromosomes and their importance in horticulture (F W Sansome) and the place of school gardening in elementary and secondary schools (T Ewing) The production of virus free seed potatoes is discussed by P A Murphy and the modified leader tree by T Swarbrick whilst the formation and development of cherries is described by M B Crane

The Royal Technical College, Glasgow

IN the building up of the world wide reputation of the 'Scots engineer the Royal Technical College, Glasgow, may fairly claim to have played a very large part, and much of this work has been done in its evening classes It is noteworthy that of all the colleges that come within the purview of the University Grants Committee, the R T C has far and away the largest number of evening students Its recently published annual report shows that, notwithstanding the transfer of the classes in music, with about a hundred students, at the end of the preceding session, to the Scottish National Academy, there was an increase in the evening student enrolment from 2,624 to 2,665, of whom a very large majority were engineering students Some indication of the exceptional range and standard of the evening classes is given by the fact that the enrolment included 100 graduates of universities of Scotland, England, Ireland, Canada India and China An important and seemingly long overdue event of the year was the formation of a Former Students Association with a membership of seven hundred and correspondents in many parts of the world The Association aims at enabling former students to retain an interest in the affairs of the College and as the honorary secretary is a member of the staff it may be hoped that it will help the College to retain an interest in the former students An important source of strength for the College is the scheme of affiliation of continuation classes conducted by eight county education authorities and attended by more than seven thousand students The Glasgow Careers Council (for Secondary Schools) co operates with the Ministry of Labour in promoting visits of boys and girls with their teacher to various departments of the College

University Studies at Jerusalem

A BULLETIN recently issued by the Hebrew University at Jerusalem discloses the fact that Polish students largely outnumber all others The total enrolment last year was 779 including 48 research students Of the undergraduates 433 were from Poland 150 from Palestine 49 from Germany, 35 from Lithuania and Latvia 17 from Rumania and the rest from 18 other countries The same bulletin contains an article by Dr Dushkin lecturer in educational method and administration on the various activities of his department including measures for improving and extending the teaching of Arabic In the Palestinian schools Arabic has been taught like Latin or Greek with stress upon the analysis of grammatical forms and translation of classic texts The University s policy is, on the contrary, to emphasize the conversational aspects of the language and to promote the employment of a minimum course for all Jewish children in colloquial Arabic, with simple reading and writing and instruction in Arabic folk ways and customs This is a difficult task owing to the prevalence of a snobbish contempt for the 'vulgar spoken language of the common people, which differs widely from the classic Arabic of literature and is not taught by the Arabs in their own schools The department is largely under the influence of American educational theory, the chair of the principles of education being held by Prof Kaplan of New York, for many years a professor at the Jewish Theological Seminary there and principal of its Teachers Institute, and a leader of the Society for the Advancement of Judaism and of the Reconstruction Movement in American Jewry

King Edward's Hospital Fund for London

THE fortieth annual report of King Edward's Hospital Fund for London, recently issued and covering the year 1936, gives an account of the finances of the Fund and of the grants recommended The ordinary distribution remained unchanged at £300 000, to which was added a first contribution of £2,000 in respect of work done for hospital out patients by district nursing associations Grants were made to 146 hospitals and 56 convalescent homes The contributions to the Fund included a capital gift of £20 000 from His late Majesty King George V The Fund has acquired an additional 7 grains of radium, thus bringing the amount under the Fund s control up to a total of 17 grams An account is given of the work of the Propaganda Committee which includes the production of a new film on hospital progress, specially suited to school audiences

Eradication of Bovine Tuberculosis

THE Register of Attested Herds in Great Britain, under the Tuberculosis (Attested Herds) Schemes which has been recently published gives particulars of the herds on the Register on December 31 At that date there were 812 attested herds with 37 000 cattle in England and Wales, and 640 herds in Scotland with 50 500 cattle a considerable increase over the previous year The Register gives the names and addresses of the owners and the breeds of cattle and can be obtained on application to the Ministry of Agriculture and Fisheries 7 Whitehall Place, London S W 1, or, for Scotland, 15 Moray Place Edinburgh, 3 The issue of a certificate of attestation is evidence that the owner of the herd has taken steps to eradicate tuberculosis from the herd, and that as a result of an official tuberculin test the herd has been found to be free from tuberculosis

Air borne Traffic and Infectious Diseases

THE Minister of Health has made regulations, similar to the Port Sanitary Regulations 1933 designed to prevent the introduction of infectious diseases into Great Britain through the medium of air borne traffic which came into force on July 1 The authorities responsible for the administration of these Aircraft Regulations are the port health authorities for aerodromes at ports and elsewhere the local authorities of the districts in which the aerodromes are situated The regulations authorize if necessary, temporary detention of aircraft medical inspection of passengers and crews, cleansing, disinfection, etc The issue of these regulations marks a further advance in the policy for the provision of health services suitable for modern conditions

The Vale of Neath

THE National Museum of Wales has initiated a series of studies of the origin of Welsh scenery with a small pamphlet on the River Scenery at the Head of the Vale of Neath , by Dr F J North The area covered is about sixty square miles and is one of great scenic charm The studies do not necessarily embody original work , but they aim at giving popular descriptions of the origin of the land forms with as little use of technical terms as possible Where technicalities are unavoidable they are fully explained The present study is a good example of intelligent popularization both in its wording and its diagrams and illustrations

Old Science and Medicine

E. P. GOLDSCHMIDT AND CO., of 45 Old Bond Street, W.1, have recently issued an illustrated and annotated catalogue of works of old science and medicine, comprising important books in the history of the mathematical and physical sciences, biology and medicine. The most valuable works figuring in the catalogue are the complete manuscript of the 'Chirurgia Magna' of Bruno de Longoburgo (1250), Pierre Franco's treatise on hernia (1561), the Aldine *editio princeps* of Galen's works in five volumes (1525), Robert Hooke's Cutlerian Lectures on physics, mechanics, geography and astronomy (1674–1678), Claude Perrault's memoirs on the natural history of animals in two volumes (1671–76) and theses by pupils of Linnæus (1749–1769) and Purkinje (1824–1840). The catalogue also contains first editions of works by Tycho Brahe, Euclid, Fracastor, Goethe, Laennec, Lamarck, Lavoisier, Napier, Röntgen, Schwann, Sirturus, Steno, Tartaglia and Willis. Modern literature is further illustrated by works by Edison, Freud, Casimir Funk, Metchnikoff, and Hugo de Vries.

Royal Anthropological Institute

THE annual meeting of the Royal Anthropological Institute was held on June 28 when Mr. H. J. Braunholtz delivered his presidential address entitled 'Ethnographical Museums and the Collector: Aims and Methods'. Two Rivers Memorial Medals for 1938 were presented, to Prof. A. R. Radcliffe-Brown for anthropological research in the fields of the Andaman Islands and Australia, and to Miss D. A. E. Garrod for work in Gibraltar, Southern Kurdistan and Palestine. The Wellcome Gold Medal for 1937 for anthropological research was awarded to Dr. Meyer Fortes for a thesis on 'Marriage Law among the Tallensi'.

World Power Conference: Vienna Meeting

THE Vienna Sectional Meeting of the World Power Conference will take place on August 25–September 2. A programme has been issued giving details of the sessions and sectional meetings, the social events planned for the participants, the sight-seeing tours and the Conference journeys. The official opening meeting in the Vienna Concert House is at 10 a.m. on Thursday, August 25, and allowing Saturday and Sunday for sight-seeing, the meeting goes on until Friday, September 2, when a second week begins devoted to tours of exceptional interest. Messrs. Thos. Cook and Son have been officially authorized to act as travel agents. Payment of all fees, which are most reasonable, can be made in English currency. The railway administrations grant substantial reductions in fares to all the participants at the Vienna meeting. Among other excursions on Monday, September 5, there will be one over the Gross Glockner Pass. This road has an almost perfect surface and owing to the wonderful road building technique, the gradient is never more than 12 per cent. It is a marvellous piece of engineering. The excursion goes to the Franz Josefs Hohe (7,370 ft.) where there is a wonderful view of the Pasterze Glacier, the longest glacier of the Eastern Alps. Full particulars of the fortnight's programme, charges, accommodation, etc., can be obtained from the Secretary, British National Committee, World Power Conference, 36 Kingsway, London, W.C.2.

Announcements

MR. H. N. SAVOURY, of St. Edmund's Hall, Oxford, and MacIver Research Student of Queen's College, has been elected by the Faculty of Archæology, History and Letters of the British School of Archæology at Rome to the Rome Scholarship for 1938. Mr. Savoury will devote the period of his tenure of the scholarship to research on certain aspects of the neolithic, bronze and early iron ages in Italy, and the influence of Italy on the lands north-west of the Alps and on Iberia during the early Bronze age.

THE Busk studentship in aeronautics, founded in memory of Edward Teshmaker Busk who lost his life in 1914 while flying an experimental aeroplane, has been awarded for 1938–39 to G. O. Jones, Emmanuel College, Cambridge.

DR. ADALBERT CZERNY, formerly professor of children's diseases in the University of Berlin, has been awarded the shield of nobility of the German Reich on the occasion of his seventy-fifth birthday.

A MONUMENT to Dr. Albert Calmette, the well-known authority on tuberculosis, has recently been unveiled at Nice.

THE Public Health Services (Engineering and Equipment) Exhibition and Congress, formerly the Public Health Exhibition and Congress, will be held at the Royal Agricultural Hall, London, on November 14–19.

THE International Congress of Light will be held at Davos, Switzerland, on July 29–30 under the presidency of Dr. Morikofer. The subjects for discussion will be light and climatology, action of natural and artificial light on healthy and diseased organs, and physiological and physical study of the therapeutic sources of light. Further information can be obtained from Dr. Schreiber, Robert Koch Platz 1, Berlin.

THE Child Welfare Information Centre of the League of Nations has published a useful "Summary of the Legislative and Administrative Series of Documents of the Child Welfare Information Centre to December 31st, 1937" (Messrs. Allen and Unwin, 40 Museum Street, London, W.C.1. 1*s*.). It contains brief details of enactments in various countries between February 1936 and December 1937 dealing with matters of child welfare.

ERRATUM. In the issue of July 2, p. 31, line 5, for "Pinex" read "Pinax".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 78.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Tides in the Upper Atmosphere

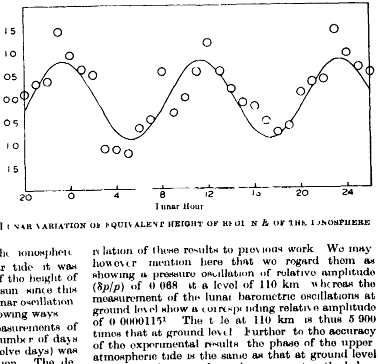
THE exploration of the physical state of the upper atmosphere by radio waves has so far been principally concerned with the investigation of the distribution of ionization and with the regularities and irregularities in this distribution due to solar control. In a series of measurements made during the past year we have endeavoured to extend the employment of radio waves to the investigation of upper atmospheric oscillations. Such oscillations would include tides produced by the gravitational influence of the sun and the moon, and would result in both vertical movements of individual air particles and also in variations of the atmospheric pressure at a given level. The influence of the moon has been examined first, since, the effect being purely gravitational, there is no need to unravel, as in the solar case, the simultaneous effects of tidal motion and varying height of ion production. Further, for various theoretical and experimental reasons attention has been confined to the level of Region *E* of the ionosphere.

For the investigation of the lunar tide it was necessary to eliminate the variation of the height of the reflecting layer with angle of the sun, since this variation is many times the expected lunar oscillation. This was accomplished in the two following ways.

(*a*) A series of quarter hourly measurements of equivalent height of reflection for a number of days (usually six to eight in a period of twelve days) was plotted to exhibit the diurnal variation. The departures from the smooth mean curve were then plotted as a function of lunar hour.

(*b*) A series of noon values of equivalent height were plotted to exhibit the seasonal variation, and the daily departures from the smooth curve were plotted as a function of lunar hour.

The accompanying diagram shows the hourly mean departure as a function of lunar hour, the full curve giving the semi-diurnal lunar variation of equivalent height as deduced from the points by harmonic analysis. The curve is derived from quarter hourly measurements made during different groups of days, throughout a period of eight months. A seasonal set of measurements has indicated a tide of the same magnitude and phase, the maxima being about ¾ hour before the lunar transits.



LUNAR VARIATION OF EQUIVALENT HEIGHT OF REGION *E* OF THE IONOSPHERE.

We hope to publish elsewhere a full account of the evidence which leads us to regard this tidal amplitude as significant, together with a discussion of the relation of these results to previous work. We may, however, mention here that we regard them as showing a pressure oscillation of relative amplitude $(\delta p/p)$ of 0.068 at a level of 110 km., whereas the measurement of the lunar barometric oscillations at ground level show a corresponding relative amplitude of 0.0000115[1]. The tide at 110 km. is thus 5 900 times that at ground level. Further, to the accuracy of the experimental results, the phase of the upper atmospheric tide is the same as that at ground level at Greenwich, a result in disagreement with deductions made from the lunar magnetic variations, assuming such variations to arise from currents flowing in Region *E*.

These experiments have been conducted as part of the programme of the Radio Research Board of the Department of Scientific and Industrial Research.

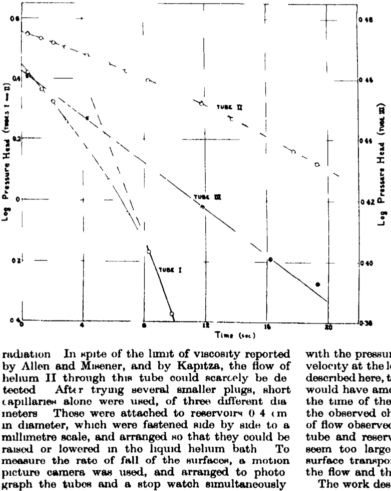
Viscosity of Liquid Helium II

IN recent experiments on the flow of liquid helium II through very small openings, carried out by Allen and Misener[1], and by Kapitza[2], an upper limit to the viscosity was placed at 10^{-9} c g s units, in definite disagreement with previous results obtained in this laboratory by Wilhelm, Misener and Clark[3] by means of an oscillating cylinder However, in none of these experiments were conditions such as to ensure laminar flow

In view of this apparent extremely rapid flow of helium II, we thought that a study of the flow as the liquid passed through the λ point would give some information concerning the rate of transformation from helium II to helium I For this purpose, a capillary tube 0 02 cm in diameter was filled to a length of 3 cm with washed emery powder, and connected to a reservoir In order to prevent the fountain effect observed by Allen and Jones[4] with a similar device, the emery plug was protected from radiation In spite of the limit of viscosity reported by Allen and Misener, and by Kapitza, the flow of helium II through this tube could scarcely be detected After trying several smaller plugs, short capillaries alone were used, of three different diameters These were attached to reservoirs 0 4 cm in diameter, which were fastened side by side to a millimetre scale, and arranged so that they could be raised or lowered in the liquid helium bath To measure the rate of fall of the surfaces, a motion picture camera was used, and arranged to photograph the tubes and a stop watch simultaneously In the first experiments the tubes were lowered into helium II at a temperature a little below the λ point, and the flow into the tubes was observed as the temperature was slowly raised through the transformation to helium I However, the change in the rate of flow on passing through the λ point was not greatly marked, and so measurements at fixed temperatures in helium II were made



In no case did the results suggest that the liquid helium II was behaving as a super fluid In the accompanying diagram the logarithm of the pressure head is plotted against the time, for a series of measurements at 2 16° K It will be seen that, for the slower rates of flow, the relation is linear, showing that the rate was nearly proportional to the pressure The viscosity has been calculated from these results, and is given in the accompanying table The values quoted are correct in order of magnitude only, since the tubes were not very uniform, and no end corrections were made Using this estimate of the viscosity, the Reynolds number has been calculated, and in all three cases is less than 1,000 for the smallest velocity measured We hope, by using more uniform tubes, to obtain more accurate values for the viscosity

Tube	Diameter (cm)	Length (cm)	Viscosity (c g s units)	Velocity for small pressure heads (cm /sec)	Reynolds number
I	0 035	1 8	$7\ 9 \times 10^{-6}$	21	750
II	0 024	1 9	$7\ 8 \times 10^{-6}$	28	670
III	0 013	1 7	$5\ 4 \times 10^{-6}$	13	170

These results are not compatible with those of Allen and Misener, or of Kapitza, but agree in order of magnitude with the earlier work of Wilhelm Misener and Clark We suggest that in the case of the long fine capillary used by Allen and Misener, the observations can be explained by the transport phenomenon studied by Daunt and Mendelssohn[5] According to the results reported by the latter the level in the reservoir used by Allen and Misener would have fallen at a rate of about 0 02 mm per second at 2 17° K due to transport over the surface of the tube This would account for the observed drop, and it seems probable that the actual flow through the long capillary was negligible This would also account for the fact that the velocity did not vary greatly with the pressure head, and for the large increase in velocity at the lower temperature In the experiments described here, the change in level due to this transport would have amounted to only about 0 1 mm during the time of the experiment less than 1 per cent of the observed change On the other hand, the rates of flow observed by Allen and Misener with a larger tube and reservoir, and that observed by Kapitza, seem too large to be fully accounted for by the surface transport, and further experiments on both the flow and the transport are highly desirable

The work described above was carried out by H E. Johns, J O Wilhelm, and Dr H Grayson Smith

Production of Secondary Electrons by Cosmic Ray Particles

SOME early measurements of Anderson and Neddermeyer[1] show that the number of single secondary electrons ejected by cosmic ray particles from a metal plate is in reasonable agreement with that to be expected from direct elastic collisions In a series of photographs we have observed the traversal of a 2 cm plate of gold by about 900 particles all of which may be assigned to the penetrating group With this gold plate, which has a thickness of 8 5 in the units of the cascade theory the behaviour of electrons can be immediately distinguished from that of the penetrating particles, and so the behaviour of the penetrating rays can be examined separately On the assumption that these penetrating rays have a mass greater than that of electrons Bhabha[2] has calculated the number of ordinary secondary electrons knocked on by collision and the subsequent cascade showers that the latter produce The particles are considered in two energy groups above and below 3×10^9 e volts previous measurements of the energy spectrum for the magnetic field and counter arrangement used having shown that 44 per cent of the observed rays have an energy greater than 3×10^9 e volts For convenience of the comparison with theory, the secondary electrons have been classified into those with energy greater and less than the critical energy of the cascade theory for gold 10^7 e volts

In the group of particles with energy greater than 3×10^9 e volts, the total number of secondaries observed with energy greater than 10^7 e volts was 4 4 per cent of the number of primary particles The corresponding number of secondaries for the energy range below 3×10^9 e volts was 0 4 per cent

The table below shows the frequency of occurrence as a percentage of the penetrating particles of (*a*) single secondary, (*b*) two secondaries (*c*) three or more secondaries

	Energy of Primary (e v)	(*a*)	(*b*)	(*c*)
		1	2	>
All observable secondaries	$> 3 \times 10^9$	3 3	0 3	0 3
	$< 3 \times 10^9$	0 8		
Secondaries of energy $> 10^7$ e volts	$> 3 \times 10^9$	2 8	0 3	0 3
	$< 3 \times 10^9$	0 4		

We observe relatively few slow secondaries, with energy loss than 10^7 e volts but this is due at least in part, to the strong scattering of these particles

The measurements give a rough indication of the mass of the main penetrating component of the rays In Fig 1 the total number of secondary particles of energy greater than 10^7 e volts to be expected from the calculations of Bhabha[2] for penetrating particles of 10 and 100 times the electron mass and for protons is shown, and the measured values for the two groups of particles are plotted These values are probably low, in comparison with the theoretical curves, since the theory does not take account of scattering, but they are sufficient to indicate a mass of the penetrating particles at least 100 m_0 and probably greater

Thus these results show that the observed number of secondary electrons can be explained by the elastic collisions of the penetrating rays with electrons, assuming that the former have a mass rather greater than 100 m_e The energy loss corresponding to this process can be seen from Bhabha's calculation to be of the order of one third of the ionization loss alone

Now for energies between 10^8 and 2×10^9 e volts, direct measurement[3, 4] has shown a much larger energy loss, of the order of ten times the ionization loss It follows that the main part of this energy loss must occur without producing observable secondaries

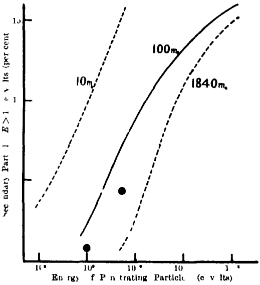

Fig 1

Fig 2 shows the production of a small shower of four electrons by a penetrating particle of high energy The fastest electron has an energy of about 3×10^7 e volts A similar photograph has been reported by Ehrenfest[5]

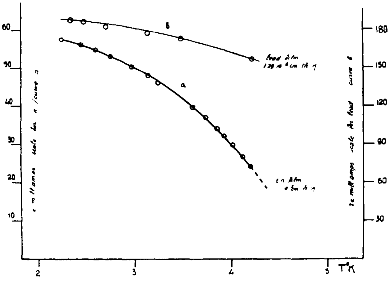
Superconducting Thin Films

We wish to report some preliminary results on the superconductive properties of lead and tin films between 5×10^{-7} cm and 2×10^{-6} cm thick, obtained by condensation from the vapour. The films were deposited on a glass surface at 4·2° K which carried four platinum electrodes, the conductivity measurements being made by means of a compensation apparatus; the film thicknesses were determined from the difference in mass of the source before and after evaporation. In order to ensure the cleanest possible conditions, the condensation and measurements were made in a sealed off high vacuum apparatus.



Even the thinnest films investigated showed superconductivity. The resistance was restored in a single abrupt jump if the measuring current was increased beyond a critical value i_c characteristic of the particular film and temperature; further increase of current produced no appreciable change of resistance. On again reducing the current, the resistance disappeared in a single jump but at a lower value of current than i_c; the whole resistance current curve could be reproduced any number of times. The value of i_c at a given temperature decreased with the thickness of the film, and was in general of the order of magnitude of some milliamperes; in all cases this was very much smaller than could be expected from Silsbee's hypothesis, supposing the critical field to be the same as for the bulk metal.

Actually, however, the magnetic fields required to restore the resistance were not lower, but much higher than for the bulk metal: thus a magnetic field even as high as several thousand gauss, applied parallel to the current, reduces the value of the critical current, but this influence is only slight (especially for the thinner films). With increase of the film thickness the magnetic field required to destroy superconductivity decreases.

The critical current decreases with increase of temperature, and in the case of tin, it was possible to estimate the transition temperature by extrapolation of the accompanying $i_c - T$ curve (Curve *a*) to zero i_c. This suggested a transition temperature of about 4·7° K for all the tin films, which is about 1° higher than for tin in bulk. For lead this extrapolation is not possible, owing to the flat course of the $i_c - T$ curve (Curve *b*), but the curve suggests that here also the transition temperature may be higher than for lead in bulk (7·2° K).

A significant feature of the results is that the superconductive properties underwent a marked change if, after deposition the films were warmed to room temperature (probably causing recrystallization), and then recooled. Thus in the case of tin the transition temperature dropped to about 3·7° K (the value for bulk tin), for a temperature equally far below the transition temperature the magnetic fields required to restore resistance became rather smaller, and i_c became rather greater.

Since all the properties (except the sharpness of the transition between super- and normal conductivity) are very reminiscent of those of superconductive alloys, it seemed that the anomalously high transition temperature of freshly deposited tin might be connected with the presence of impurities; variation of cleanliness of the condensation conditions however caused no change of the high transition temperature, so it is likely that this is genuinely characteristic of the *structure* of films deposited at 4·2° K. How far the other anomalous properties are connected with the structure and how far with the thinness of the films must remain a question for further investigation, but the results so far, suggest that the structure can scarcely be responsible alone.

Melting and Structure of Long-Chain Ketones

A number of isomeric long-chain ketones have been prepared and specially purified in the course of investigations on the solid liquid transition in long chain compounds[1]. As will be clear from the diagram for the ketones $C_nH_{2n+1}COC_{(16-n)}H_{33-2n}$ the setting points depend in a remarkable way on the position of the CO dipole in the long chain molecule. The maximum difference (between $C_8H_{17}COC_8H_{17}$ and $C_5H_{11}COC_{11}H_{23}$) of 9·2° may be compared with the difference in setting points between $C_5H_{11}COC_{11}H_{23}$ (s.p. 40·8°) and the corresponding paraffin $C_{17}H_{36}$ (s.p. 21·6°).

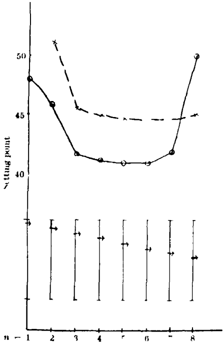
In order to verify that this behaviour is not confined to chains with an odd number of carbon atoms, ketones of the series $C_nH_{2n+1}COC_{(17-n)}H_{35-2n}$ have also been prepared, and show a corresponding behaviour. A survey of published melting points of other ketones suggests that this effect is quite general.

In view of the comparatively simple crystal structure of long chain compounds[2,3], these observations are of interest for theories and mechanical models of the melting of crystal lattices. A detailed analysis of the crystal structure of a long chain ketone has not yet been achieved partly owing to the lack of suitable single crystals The comparison of X ray powder photographs of ketones with the corresponding paraffins shows however, that the introduction of the CO dipole only leads to small changes in the side spacing of the chains, when these are sufficiently long For compounds of the series $C_{17}H_{36}$ the lattice dimensions are

	a	*b*	*c*
$C_{17}H_{36}$	7·63	4·91	23·26
$C_{17}H_{34}O$	7·55 ± 0·01	4·79 ± 0·06	23·26

and any differences between the isomeric ketones are within the errors of measurement In view of the intensity determinations on X ray powder photographs of ketones due to Shearer it may be assumed that the chief difference between the lattice of a paraffin and a ketone is the presence of layers of dipoles in the latter Except in the methyl ketones, the potential energy of dipoles in a layer is apparently without influence on the potential energy in other layers A check on this assumption is obtained from the measurement of the latent heats of fusion obtained from cryoscopic data The latent heats of fusion are

$C_{17}H_{36}$ 10·0 k cal /mole
$C_{17}H_{34}O$ 13·5 ± 0·4 k cal /mole



DATA FOR $C_{18}H_{36}O$ CROSSES $C_{17}H_{34}O$, CIRCLES

In the case of the isomeric ketones, deviations from the mean value do not seem to be connected in any systematic way with the position of the dipole, and are probably due to experimental errors The results merely show the additional heat of fusion required to break up the dipole layers

Since the dynamical properties of the paraffin and ketone lattices must be closely similar, a possible explanation of the variation in setting point in isomeric ketones may perhaps be given on purely mechanical grounds On melting, the thermal motion of the chains has not only to overcome the orientation energy due to van der Waals forces, which will be similar to those in the paraffin but has also to overcome the orientation energy in the dipole layers If the long chain molecules are compared with an assemblage of rods undergoing torsional vibrations and clamped to one another at a position along the rod corresponding with the position of the dipole it seems likely on account of the properties of stationary vibrations that the minimum interaction on the clamping will be found when this is situated either symmetrically in the middle or at one end In other words the thermal motion of the molecules required to overcome the orienting forces in the dipole layer must be bigger when the layer is situated at a point in the chain where torsional vibrations are less efficient in leading to motion

This interpretation of the experimental results in terms of a mechanical model can only be regarded as provisional Obvious limitations arise from the fact that electrical[4] and thermal[1] properties of long chain compounds indicate extensive premelting and at least a partial freedom of orientation of the molecules below the melting point Nevertheless the latent heats of fusion indicate that considerable orientation of the dipoles must persist in the solid A further limitation may arise owing to differences in details of the structure of isomeric ketones not evident from powder photographs, though the structural and thermodynamic evidence does not leave much scope for uncertainty Experiments are being made with other compounds in order to test more fully the various factors which determine a transition from solid to liquid

A Heat-Labile Isomer of Vitamin A in Cod Liver Oils

IT was observed during experiments involving the keeping properties of an individual cod liver oil that the value of $E^{1\%}_{1\,cm}$ 328 mμ determined on the unsaponifiable fraction spontaneously increased, on keeping to a maximum after several weeks, but the total absorption determined directly on the oil did not increase The oil had an initial $E^{1\%}_{1\,cm}$ 328 mμ value of 0·60 when determined on the unsaponifiable matter, and 0·60, 0·62, 0·63, 0·65 and 0·54 after 1 4, 5, 8 and 14 weeks respectively, whereas the determination on the original oil of 0·70 gave figures of 0·70, 0·69 and 0·67 after 1, 8 and 14 weeks With tests performed on the oil itself, both by spectrographic means and colour reaction, spontaneous increase in the apparent vitamin A has been noted by others[1] and has been assumed due to extraneous substances such as free fatty acids[2,3]

From the observation that the $E^{1\%}_{1\,cm}$ 328 mμ value increases spontaneously, it follows that either there is a chromogen present transparent at 328 mμ which is being converted to the normal vitamin A or there is a factor present giving absorption at about 328 mμ which is sensitive to heat and is destroyed during saponification. The former supposition cannot be correct since the gross absorption does not increase simultaneously but, in fact, remains practically constant. In the latter event isomerism would most likely account for the increase of the vitamin A with time. Smith, Stern and Young[4] have suggested the possibility of an isomeric factor of the *cis-trans* type being present in concentrates.

Experiments appear to confirm the presence of a heat-labile factor; when using cold saponification followed by cold evaporation of the ethereal solution of the extracted unsaponifiable matter, higher values for $E^{1\%}_{1\,\mathrm{cm}}$ 328 mμ are obtained. Tests have been made on genuine cod liver oils examined as soon as possible after extraction; some of the results, typical of the whole, are given in the accompanying table.

		A	B	C	D
Direct on oil	Day received	0·94	0·[illegible]8	1·0[illegible]	0·[illegible]2
	After 1 week			1·08	
	2 weeks	0·93	0·60		
	4 "	0·89	0·62		0·[illegible]6
Via hot unsap.	Day received	0·81	0·53	0·8[illegible]	1·47
	After 1 week	—		0·84	
	2 weeks	0·86	0·[illegible]8	—	
	4 "	0·[illegible]1	0·[illegible]8		1·49
Via cold unsap.	Day received	0·96	0·[illegible]8	0·9[illegible]	[illegible]
	After 1 week			1·06	
	2 weeks	1·03	0·60		
	4 "	0·[illegible]8	0[illegible]		0·[illegible]4

Deterioration set in fairly rapidly under the particular conditions of storage, namely, full bottles at room temperature in the dark, but the figures for cold saponification generally remained above those for the hot saponification method.

Heat evaporation of the solution of extracted cold saponification unsaponifiable matter and also boiling the oil with alcohol lowered the figure for the value of $E^{1\%}_{1\,\mathrm{cm}}$ 328 mμ in comparison with that obtained by cold saponification and cold evaporation.

The possibility of an enhanced 328 mμ absorption in the cold saponification method being due to extracted impurities difficult of volatilization at low temperatures was eliminated by experiment.

If the isomeric chromogen should prove biologically active, it follows that the value for $E^{1\%}_{1\,\mathrm{cm}}$ 328 mμ obtained directly on the oil would be, at least for fresh oils, a more correct indication of the vitamin content, although after general deterioration of the oil impurities take effect and the test on the unsaponifiable matter obtained by cold saponification would have to be used.

It is hoped that full details of the experiments and further work nearing completion on this problem, including the effect of accelerators, light and temperature, will shortly be published elsewhere.

Mechanism of Fructose Resorption in Intestine and Kidney

As demonstrated by Cori[1], fructose is absorbed from the intestine definitely more slowly than galactose and glucose. If an intermediary formation of hexose phosphoric acid is an essential factor in the active absorption of sugars[2] it must be assumed that either the phosphorylation of fructose or the dephosphorylation of fructosephosphoric acid (or both reactions) proceeds with a definitely lower velocity than the corresponding reactions of glucose and galactose. The phosphorylation of fructose in kidney extract takes place at precisely the same rate as the phosphorylation of glucose[2]. The question now is whether fructosephosphate is dephosphorylated at a slower rate than glucosephosphate?

In an interesting paper of Goda[3] it is demonstrated that the complete conversion of fructose into glucose in the liver tissue depends on a peculiar selective dephosphorylation of the glucose component in the Embden ester; in other words, fructosephosphoric acid is not directly dephosphorylated, but only through conversion into glucosephosphoric acid.

It is suggestive to suppose that this indirect dephosphorylation of fructosephosphoric acid is the reason for the relative slowness of fructose resorption in the intestine.

I have tried to demonstrate the Goda effect in extracts of intestinal mucosa and kidney cortex.

CHANGES IN CONTENT OF ALDOSE AND KETOSE DURING ENZYMIC DEPHOSPHORYLATION OF EMBDEN ESTER

	Min.	Per cent dephosphoryl.	Aldoses	Ketoses
Intest. mucosa	60	7[illegible]	3·[illegible]8	3·[illegible]
Intest. mucosa	3[illegible]	67	2·24	3·04
Intest. mucosa	60	80	3·0[illegible]	3·34
Kidney extract	60	7[illegible]	+ 2·30	1·[illegible]

In the kidney extract no fructose at all was liberated whereas in the mucosa extracts a part of the phosphorylated fructose was liberated.

The selective dephosphorylation was not demonstrable in concentrates of intestinal and kidney phosphatases (Albers and Albers preparations[4]) but is evidently a characteristic of the fresh tissue. That the intestinal mucosa really converts glucose into fructose appears from the data of Oppel[5]. According to Verzar[6] fructose when given in high concentrations is partly actively absorbed into the blood through a conversion into glucose, partly diffuses passively.

The cause of the slowness of absorption of fructose in the intestine seems therefore to be not a slow phosphorylation of fructose but a slow dephosphorylation of the fructose 6 phosphate.

Nicotinic Acid and the Fermentation of Dextrose by the Colon-Typhoid Group of Bacteria

NICOTINIC acid has recently assumed special importance as a vitamin for certain bacteria, animals and man. Knight[1] has shown that nicotinic acid is an essential factor for the growth of *Staphylococcus* *aureus* During the same year it was demonstrated that this substance cures black tongue in dogs and pellagra in man[2,3]

The object of our studies was to ascertain whether nicotinic acid is essential for the growth of the pathogenic members of the colon typhoid group The results show that although *Shigella dysenteriae* (Shiga and Flexner) and *S Paratyphosus* A can grow in the simple peptone medium described below the addition of nicotinic acid is essential for their active utilization of dextrose

The basic medium was made up as follows

(*a*) Salt solution

NaCl	0 [illegible] per cent
Na_2HPO_4 $2H_2O$	0 2
KH_2PO_4	0 03
$MgCl_2$ $6H_2O$	0 03
Traces of iron and manganese	

These salts were dissolved in distilled water and filtered through a Seitz filter

(*b*) To this salt solution were added sterile solutions of peptone dextrose and nicotinic acid as desired

In one type of experiment 0 25 per cent peptone and 0 1 per cent dextrose were added to the salt solution To one set of tubes 10 γ nicotinic acid was added for each c c of medium while another set of the same lot served as controls The two sets of tubes were inoculated with the same number of organisms and incubated for twenty four hours at 37 C Growth occurred in both sets of media The dextrose content was examined by the Ellmann Maquenne method The uninoculated control contained 8 37 mgm the culture without nicotinic acid 6 29 *mgm and that with nicotinic acid* 0 93 *mgm* of dextrose per 9 c c of media

In another type of experiment we varied the amount of peptone To one set of tubes was added 10 γ of nicotinic acid per c c while to the other set no nicotinic acid was added The sugar content of the various tubes after 48 hours incubation was as follows

Per cent peptone	With nicotinic acid mgm dext 9 c c	Without nicotinic acid mgm dext 9 c c
1	3 99	[illegible]
2	0 [illegible]	[illegible]
3	0 [illegible]	[illegible]

These and other data show that although the dysentery bacilli and paratyphoid A grow in the peptone glucose medium to which no nicotinic acid has been added, the glucose content is only slightly diminished even after forty eight hours incubation The addition of nicotinic acid stimulates the prompt and active utilization of the glucose with the formation of acid The nicotinic acid apparently acts as a cozymase It should be noted that even in media containing nicotinic acid paratyphoid *A* ferments glucose with the production of acid but fails to produce gas Paratyphoid *B* on the other hand ferments glucose with gas production in the medium without nicotinic acid (behaving in this respect like *B coli*) The enzymic systems of the two species of paratyphoid are thus fundamentally different

Phytohormones and Seed Disinfection

THE formaldehyde method of disinfecting cereal seeds for smuts often results in substantial reduction in germination and in retarded growth It has been found that the addition of 1/100 10 ppm of phytohormone chemical to the treating solution greatly reduces or entirely prevents formaldehyde damage This effect is obtained with 3 indolylacetic *l* naphthyl acetic and phenylacetic acids and with a number of other physiologically active chemicals Certain plant extracts and vitamin B_1 also reduce this type of seed injury The accompanying photograph illustrates the effect of adding phytohormones to formaldehyde solution of standard concentration (1 part 40 per cent formaldehyde to 320 parts water)

Rewari wheat planted in soil 1 day after formaldehyde treatment Plants washed out and photographed 19 days after planting Each group represents the total number of plants grown from [illegible]0 seeds Left to right control (untreated) formaldehyde formaldehyde with 1 10 ppm 1 naphthylacetic acid formaldehyde with 1 ppm 3 indolylacetic acid

The damage caused by disinfecting seed with copper sulphate and mercuric chloride is also reduced by the addition of a small amount of phytohormone By a similar method marked improvement is produced in the germination and growth of seed treated with hot water for smut control The use of these active chemicals as an accessory to seed disinfection may thus be of value in agricultural practice It has also been found that these responses of seed to physiologically active chemicals may be used to indicate the activity of new chemicals and extracts

A more detailed account of this work will appear shortly in the *Canadian Journal of Research*

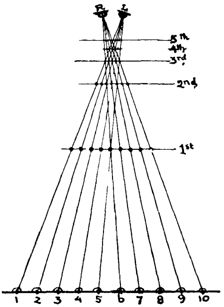
A Binocular Illusion

THE following may be added to Dr R S Creed's letter in NATURE of May 28 p 977

In the case of a well defined pattern for example, alternate squares of black and white, the distance between centres of the pattern being about equal to that between the observer's eyes it is easy to make the 'suspended' pattern appear at any one of five different distances. With the original pattern about 90 cm. distant, the nearest suspension (in my own case) is at about 9 cm. from the eyes—the others being at about 11·5, 15·5, 22 and 42 cm. respectively.



The distance of the suspension depends on the degree of convergence of the eyes and is most easily adjusted by fixing the eyes on, say, the observer's own thumb nail and moving it to and fro in front of the patterned surface. At about the distances mentioned the observer's thumb suddenly seems to be floating on the suspended surface. The apparent size of the pattern decreases in proportion to its apparent distance from the eyes.

The principle involved is shown in the accompanying drawing. At the first suspension the right eye R is looking at element 6 of the pattern while the left eye L is looking at 5, while the observer's mind assumes that both eyes are looking at the *same* element: the pattern is therefore seen suspended at the distance at which the two lines of sight converge. In the 5th suspension, R is looking at element 10 while L is looking at element 1.

It seems clear that in these experiments the angle of convergence of the eyes is the determining factor in producing the illusion of distance.

Points from Foregoing Letters

Prof. E. V. Appleton and K. Weekes have shown the existence of a lunar tide in the Kennelly-Heaviside layer which is accompanied by a relative pressure oscillation 6,900 times as large as the corresponding lunar pressure oscillation at ground level.

A table and graphs showing the rate of flow of liquid helium II through capillary tubes, as determined by H. E. Johns and J. O. Wilhelm and Dr. H. Grayson Smith, are submitted by Prof. E. F. Burton. The results differ from those of Allen and Misener and of Kapitza in showing a normal rate of flow without any tendency to super-fluidity.

From the number and energy of secondary electrons produced by the more penetrating cosmic ray particles traversing a 2 cm. plate of gold, J. G. Wilson, using Bhabha's calculations, concludes that the observed number of secondary electrons can be explained by the elastic collisions of the penetrating rays with electrons, assuming that the former have a mass rather greater than a hundred times that of the electron.

Dr. A. Shalnikov reports anomalous properties of superconducting lead and tin films condensed on to glass at 4·2° K. The transition temperatures were higher than for the bulk metals, the currents required to restore resistance were much lower than those predicted by Silsbee's hypothesis, and the magnetic fields required to restore the resistance were much higher than for the bulk metal. All these anomalies were modified if the film was warmed to room temperatures and re-cooled, and for tin the transition temperature became about the same as for the bulk metal, so it is probable that the anomalies are partly connected with the structure of the films.

Experimental values are given by Dr. A. R. Ubbelohde and J. W. H. Oldham for the setting points of isomeric ketones of the general formulæ $C_{17}H_{34}O$ and $C_{18}H_{36}O$. The setting points are considerably higher when the carbonyl group is at one end or symmetrically in the middle of the chain. A possible interpretation of these observations, in terms of a mechanical model, is considered in the light of the structural and thermodynamic evidence.

From the observation that in a cod liver oil the absorption at 328 mμ determined on the unsaponifiable fraction increases spontaneously with age, whereas the gross absorption of the oil does not increase simultaneously, Dr. D. C. Garratt infers the presence of an isomer of vitamin A which is being converted to the normal form but is destroyed by saponification. Cold saponification experiments tend to confirm this supposition.

Experiments by H. Kalckar on the rate of dephosphorylation of Emden ester by fresh tissue of intestinal mucosa and kidney extract indicate that the cause of the slowness of absorption of fructose in the intestine is not a slow phosphorylation of fructose but a slow dephosphorylation of the fructose-6-phosphate.

I. J. Kligler and N. Grosowitch find that although the dysentery and paratyphoid bacilli can grow in peptone-glucose media in the absence of nicotinic acid they cannot in those circumstances utilize glucose. Paratyphoid *B*, on the other hand, needs no nicotinic acid in order to utilize glucose.

Photographs are submitted by N. H. Grace showing that the addition of very small amounts of plant hormones (3-indolylacetic acid, *l*-naphthylacetic acid and phenylacetic acid) to wheat grains which have been disinfected with formaldehyde, reduces or prevents the slowing down of germination and growth which otherwise follows disinfection.

Research Items

Tokelau Islands

THE culture and ethnology of the Tokelau Islands, a group of four islands south of Samoa and east of the Ellice Islands, was studied during a two months visit by Mr. Gordon Macgregor from October until December 1932 (Bernice P. Bishop Museum Honolulu *Bull.*, **146**, 1937). Study of the culture shows that in its linguistic, social, religious, mythological and material phases many features are common to cultures of eastern Polynesia, but have no further distribution in western Polynesia, except in the neighbouring Ellice Islands. Of the material traits in particular many with eastern affinities are found in western Polynesia, in contradiction to the theoretical western material culture complexes put forward by previous writers. Hiroa, who has made the latest grouping of Polynesian material, has shown that a fundamental culture is common to both eastern and western islands. The analysis of Tokelau culture is summarized as follows. A migration of people moving through Micronesia passed through the Tokelau Islands and into the eastern Polynesian area. This people left a small number of their group in the Tokelau Islands where they were the first settlers and the bearers of the so called eastern Polynesian culture traits now found in the Tokelau culture. A movement of people from Samoa to the islands of the north west, through which their ancestors had probably come to settle Samoa, reached Fakaofu, introducing Samoan culture, and ultimately conquering the whole group. During the whole period of settlement of the Tokelau Islands there was a small but constant drift of Polynesians brought by the trade winds from the eastern area who introduced locally developed eastern cultural traits and reinforced the early culture. There developed in the Tokelau Islands, and the Ellice Islands as well, a culture based on the early forms of eastern culture, later influenced by Samoan, or western Polynesian culture, and perhaps slightly by Micronesian cultures, which took on a form unique in Polynesia, and which must be considered a sub culture in the western area, and in the future distinguished from the phrase "western Polynesian culture".

Anthropometry of Racial Hybrids

AN anthropometric study of certain hybrid populations has been made by Mr. J. C. Trevor (*Eugenics Rev.*, **30**, No. 1). The nine populations chosen for analysis included 113 Norfolk Islanders, descendants of the *Bounty* mutineers, half blood Sioux, Ojibwa whites, 880 Yucatecans, Jamaican 'browns', American Negroes, Boer Hottentot crosses, East Indian Mestizos and Anglo Indian mixtures. Difficulty was found in obtaining comparable statistics of the parent races, and in no case could the F_1 be directly compared with the parents. Nevertheless certain significant results emerge. Comparative analysis shows that where the parental types differ markedly in any quantitative feature, such as head length or nasal breadth, the mean of the hybrids is generally intermediate, although sometimes almost coinciding with one parent. The variabilities of the hybrid population follow approximately the normal curve and appear to be unimodal. They are not, on the whole, peculiarly high or low. These results are not perhaps genetically surprising if the parent populations are themselves highly heterozygous and variable. A study of F_1 individuals from some racial cross in direct comparison with their parents would throw light on some of these questions.

Cell Size

A SERIES of careful measurements of the sizes of human lymphocytes under different conditions is utilized by Donald Mainland and Basil K. Cody (*J. Anat.*, April 1938) as a basis for a useful discussion of the significance of cell measurements. This is important since subsequent to the large amount of work done on this subject at the beginning of the present century scepticism has been expressed as to the value of such measurements. The blood was obtained from two healthy young men, and the measurements of about a hundred examples from each preparation were taken. The specimens were prepared in various ways, the ordinary control method followed by Wright's stain, mixing before drying with isotonic saline, hypotonic saline and isotonic formaldehyde. Spreading the film between cover glasses it was found that those on the lower cover glass were on the average $0\cdot56\mu$ greater in diameter than those on the upper. This the authors attribute to the more rapid falling of the larger lymphocytes. The noteworthy variation in size between the lymphocytes obtained in twenty nine films from the same individual cannot be due to controllable differences in technique. In comparing the differences obtained by the film method and mounting in isotonic saline, it was found that there was much greater variability within and between the films than in the saline preparations so that the latter furnish a more satisfactory basis for comparative observations.

Water-Absorbing Area in the Grasshopper Egg

MANY insect eggs appear to require for development an intake of additional water and oxygen from the medium surrounding them, and Bodine, in 1929, demonstrated that the increase in weight of the egg of the grasshopper, *Melanoplus differentialis*, as it develops is due to an actual increase in water content. The chitinous cuticle of the grasshopper's egg is, however, resistant to wetting and impermeable to fluids, though gases may diffuse through it, so that some special mechanism must exist for the absorption of water. Eleanor H. Slifer finds that at the posterior end of the egg a small circular area is present in the cuticle which, in contrast with the rest of the cuticle, becomes excessively thin and transparent on treatment with caustic potash solution (*Quart. J. Micro. Sci.*, **80**, Part 3, 437, 1938). In this area, termed the 'hydropyle', there is a number of large cells, different from those elsewhere, and evidently constituting a secretory organ by means of which water is taken into the egg. If at an early stage of development the hydropyle is covered with water impermeable material, development is stopped. During the twenty five days' development at 25° C., the weight of the egg nearly doubles.

Fertilization in the Onychophora

IN some species belonging to the family Peripatidæ, the males form large spermatophores which are supposed to be deposited in the female genital opening In *Peripatopsis* however the spermatophores are deposited anywhere upon the body of the female and their route thence to the ovaries has remained problematical, though the subject of ingenious speculation Dr S M Manton has solved the problem and the solution is different from the speculations (*Phil Trans Roy Soc London* B, **228**, No 556) After a spermatophore has been deposited upon the skin of a female leucocytes invade the ectoderm and the cuticle of the body and the lower wall of the spermatophore rupture Through this breach, the spermatozoa swim and so reach the vascular spaces By their own activity they pass through the hæmocœl and reach the ovary through the wall of which they force their way to the ovarian lumen where oogonia are lying freely Sperm heads invade the cytoplasm of the oogonia which divide to form ova and these absorb the sperm heads and grow In the meantime the spermatophore wall remains attached to the cuticle and closes the wound caused by the entry of the spermatozoa In the ovary the spermatozoa apart from fertilizing ova provide the early ova with food needed for their growth, and they may also supply the animal itself with nourishment or other special substances

Mycorrhiza in Garden Plants

THE mycotrophic habit has been shown to be of wide occurrence in many families of plants and now M A Mostafa has shown that *Tropæolum majus* L *Phlox Drummondii*, *Verbena officinalis* L and *Clerodendron inerme* Gaertn Hook show well developed endotrophic mycorrhiza when growing in a soil which is alkaline and of a low humus content Detailed observations of *Tropæolum* and *Phlox* have recently been published by the author (*Ann Bot* New Series **2** No 6 481 April 1938) The mycotrophic habit of both these species was shown to be very similar In neither case was the fungus found in the aerial portions of the plant From *Tropæolum* two species of *Aspergillus* three of *Penicillium* and single species of four other genera of fungi were isolated , from *Phlox*, two species of *Penicillium* one of *Fusarium* and one of *Alternaria* were obtained The fungus, outside the piliferous layer, was septate , it became septate and showed an increase in diameter of hypha after penetrating the root Aseptic seedlings (obtained by treatment of seeds with mercuric chloride) of *Tropæolum* raised either in sand or agar cultures produced a well developed root system but no fungus

Variation in Keeping Quality of Apples

AT a meeting of the Industrial and Agricultural Research Section of the Royal Statistical Society on Thursday, May 26, Mr T N Hoblyn read a paper entitled A Study of the Variation in Keeping Quality of Apples in Store as illustrated by the Behaviour of the Variety McIntosh Red from an Ontario Apple Orchard ' Keeping quality is markedly influenced by cultural treatment, but even in an orchard receiving uniform treatment considerable variability occurs Mr Hoblyn described an attempt to evaluate such variability and to elucidate the factors affecting keeping quality Samples of fruit were taken from similar trees in different positions in the orchard from trees showing varying degrees of winter injury and from trees showing inherent variability Samples from the same trees were further divided into categories according to colour and size The fruit was kept for eight months in two similar storage chambers, one at 36° F and the other at 32° F , the effect of position in the store being allowed for in the experimental design 11 520 individual apples were examined with particular reference to two forms of low-temperature breakdown, namely core flush and superficial scald' Analysis of the data showed that samples from the same tree may be extremely variable but that samples from different trees vary even more Inherent differences between trees were more important than those due to position or degree of winter injury Core flush in apples from the same tree varied with size and colour, small red apples showing least Scald, on the other hand was associated most with green apples irrespective of size The variability was discussed, and possible methods of sampling for use in different types of storage experiment were suggested

Major Spiral of the Chromonema

BY comparing normal, desynaptic and asynaptic *Trillium*, C L Huskins and G B Wilson in 1937 showed that the three following factors play a part in causing changes in direction of the major spiral of chromonema (1) chiasmata (2) the attachment (3) random changes which may be expected to be proportional to the number of gyres which the chromonema forms The authors have now published the data in detail (Probable Causes of the Changes in Direction of the Major Spiral in *Trillium erectum* L *Ann Bot* New Series **2** No 6, 281 , April 1938) From the analysis of these data it appears that (*a*) chiasmata may cause a number of changes equal to the chiasma frequency , (*b*) the direction of coiling is random on either side of the attachment, and this will cause half as many changes in direction as there are chromatid attachments, (*c*) the remaining number of changes is proportional to the number of gyres

Protective Insecticides and Fungicides

E Fajans and H Martin (*J Pom and Hort Sci* , **16**, 14 , 1938), in continuation of their work on the physico chemical properties which determine the retention of spray fluids and the tenacity of spray deposits, have examined sprays consisting of emulsions (liquid/liquid systems) and of added suspensions (liquid/liquid/solid systems) The initial retention of emulsions was found to be determined by the properties of the aqueous phase and intermediate between that of the emulsifier solution alone and that of water Preferential retention of the oil phase increases as the emulsifier concentration is reduced, and is dependent on the character of the latter Retention of emulsion suspension systems is markedly affected by the extent of interaction between the emulsifier and the solid phase, which results in partial or complete adsorption of the oil phase by the solid, which is flocculated to large agglomerates The stability of the emulsion is thus reduced with consequent increase in the extent of preferential retention of the oil phase followed by preferential retention of the solid phase The tenacity of deposits from emulsion suspension sprays is favourably affected by the presence of oil but may be reduced by the emulsifier for example, sulphite lye Owing to the necessity for using sprays of high stability, only emulsion suspension systems showing little or no interaction between emulsifier and solid can be recommended for practical use Sulphite lye is the most suitable from this point of view, and its unfavourable effect on tenacity may be reduced by reducing its concentration

Lunar Periodicity of Earthquakes

In a recent paper (*Union Geol Geoph Intern Publ*, Ser A, fasc 15, 241 257 1937) H T Stetson has studied the frequency of earthquakes in connexion with the hour angle of the moon During the years 1918 29 2 569 earthquakes were recorded at stations more than 80 from the origin Arranging these according to the hour angle of the moon referred to the meridian of the epicentre of each earthquake, he finds two maxima of frequency at 7 and 18 hours For the smaller district consisting of the Philippines and Japan the maxima occurred at 6 and 21 hours Again for 113 deep focus earthquakes, with depths of 100 km or more below the surface the maxima were at about 5 and 16 hours and the curve representing the means of the numbers of earthquakes for lunar hourly intervals corresponds closely with the curve of the east and west component of the lunar tidal force

Thermometry below 1° K

It is known that magnetic susceptibility is not appreciably useful for the purpose of denoting temperatures in the presence of any considerable magnetic field and in many cases it is undesirable to remove the field even for short intervals in very low temperature work W F Giauque J W Stout and C W Clark (*J Amer Chem Soc* **60** 1053 1938) have investigated the possibility of using the electrical resistance of finely divided amorphous carbon and their results show that this method will be very useful at temperatures below 1° K At 1 63 K a carbon ink film on glass had an electrical resistance 13 700 times that at 293° K, and the rate of increase with lowering temperature was accelerating so rapidly at 1 63 that a form of carbon with a smaller temperature coefficient of resistance was desirable The construction of amorphous carbon thermometer heaters from lampblack is described and the resistance of a carbon thermometer from 293° to 0 129° K was measured at these temperatures it was 28 062 and 58 640 ohms, respectively One thermometer was studied over a year and its resistance was found to be constant to one per cent after initial stabilization had occurred The increase of resistance in a magnetic field was measured at 4 2° and 1 5° K It was found to be larger at the lower temperature and proportional to the square of the applied field at both temperatures

Absolute Configuration of Optically Active Substances

A USEFUL review of the methods of determining the absolute configuration of optically active substances, and of progress made within recent years, has recently been given by W Kuhn (*Naturwiss*, **26**, 289, 305, 1938) The methods are discussed in connexion with inorganic compounds, potassium cobaltic oxalate $K_3Co(C_2O_4)_3$ being taken as an example The Cotton effect in the neighbourhood of the absorption bands and the oscillations of the various atoms and groups in the molecule are considered and it is shown how the configuration is arrived at Organic compounds are then dealt with starting with methyl ethyl carbinol and proceeding to compounds which can be derived structurally from this compound

Specific Ionization of Cosmic Ray Particles

D R Corson and R B Brode (*Phys Rev* **53** 773 1938) have examined a number of cloud chamber tracks of cosmic ray particles in which the ions were spread sufficiently to enable them to be counted In spite of this spreading of the tracks the energy of each particle could be measured with reasonable accuracy by its curvature in a magnetic field The particles examined were in the energy range 0 2 40 Mev they were therefore slow on a cosmic ray scale The theory of Bethe gives in this region a minimum ionization at about 2 Mev followed by a slow rise at higher energies This rise has now been found experimentally for the first time It amounts to between 10 per cent and 20 per cent for the fastest electrons studied The paper also contains an examination of the more heavily ionizing cosmic ray tracks observed by the authors themselves and by others There is a relation between the mass of the particle the curvature of the track the density of ionization, the residual range and the rate of change of velocity with distance such that any two of these quantities determine the others This is expressed in a nomogram and it is shown that nearly all the published data on heavy tracks agree with a mass 200 50 times the mass of an electron

Direct Evidence for the Neutrino

For many years the existence of a neutral particle of electronic mass has been invoked to explain the continuous energy spectrum of β rays from radioactive nuclei On this view the energy of all β disintegrations is the same and when a low energy β particle is emitted the excess energy is given to the neutrino H R Crane and J Halpern (*Phys Rev* **53** 789 1938) have investigated the recoil of the radioactive nucleus in β disintegrations and have shown that momentum relations indicate the participation of a third body A radioactive gas (a compound of radio chlorine) was introduced into a cloud chamber The track of the recoiling nucleus was too short to be measured but the expansion chamber conditions were adjusted so that the ions produced by the recoil particle formed a cluster of droplets which could be counted The number of droplets counted was examined as a function of the electron energy and it is found that where a low energy electron is emitted the momentum carried off by the *recoiling nucleus is much larger than required to* balance the momentum of the electron Control experiments were carried out with a compound of radio phosphorus, which has a much lower upper limit to its β spectrum, and very few of the tracks had detectable clusters at their origin This is held to confirm the identification of the cluster with the track of the recoil nucleus

The National Physical Laboratory

Inspection by the General Board

THIS annual event was held on June 28, when a large number of visitors representative of numerous academic, technical and commercial institutions throughout the country were received by Sir William Bragg, chairman of the Board, Lord Rayleigh, chairman of the Executive Committee, and Dr W L Bragg, director of the Laboratory The Laboratory was thrown open to the visitors and special exhibits demonstrating the work in progress were staged in its various Departments The time available does not permit the visitor to see all the exhibits, but amongst those of more recent or important the following were noted

PHYSICS DEPARTMENT

The section of the Physics Department concerned with the thermal properties of materials covers a wide range both of materials and temperatures, some of the extreme examples being typified by apparatus for measuring the thermal conductivity and latent heat of fusion of refrigerants, and another for measuring the thermal properties of steels and other alloys up to temperatures of the order of 1000° C The value and convenience of electrical methods of heat production and temperature measurement were well appreciated by a glance through the exhibits in this section

The Acoustics Section is tackling a number of problems which will eventually contribute to the comfort of a large proportion of the population by the elimination of unnecessary noise A thorough analysis of the noise emitted by a motor-cycle engine when running under various loads and silencing conditions has begun in a small laboratory which has just been built for these tests The work on architectural acoustics has largely centred of late on methods of avoiding the transmission of sounds throughout large buildings such as blocks of flats or offices. In one exhibit, a slab of acoustically insulating material such as might be built into the walls of a building was clamped between two plane surfaces one of which was driven at any desired frequency or amplitude The ratio of the amplitudes of vibration of the driver and driven surfaces was determined for various frequencies and clamping pressures

The work which has been in progress for several years in the Radiology Section on tooth structure has employed micrographic, radiographic, and X-ray analytical methods of investigation Tooth enamel has been found to possess a prismatic cell structure, and X-ray analysis has shown that these prisms contain preferentially oriented crystallites of an apatite (probably hydroxy-apatite) the hexagonal axes of which bear a definite angular relation to the axis of the prism in which they lie. The radiographic examination of sections of teeth has also revealed the distribution of their calcium content, and the changes in this distribution consequent on injury or attrition of the enamel at any point have been studied.

A new A C. bridge circuit has been developed in the Electrical Standards Section, by which capacitance and power factor can be determined in terms of the fundamental standards of mutual inductance and resistance A completely screened variable sub standard mutual inductance incorporating a compensating circuit, which ensures perfect quadrature of secondary E M F and primary current, forms an essential part of the apparatus The equipment is designed for measurements on capacitances ranging from 500 μμ F to 4 μ F, and the limits of error at 1,000 cycles per second are of the order of ± 3 parts in 10^5

The Electrotechnics Section still has a considerable amount of work in hand in connexion with the testing of substandard apparatus for supply authorities throughout Great Britain, and reflecting dynamometer wattmeters have been installed to facilitate the progress of the A C instrument testing, which has hitherto been carried out entirely with electrostatic instruments In the High Voltage Laboratory a new battery of condensers for the generation of transient currents of the order of 100,000 amperes was shown in operation

A portable telephotometer which has been in use for some years for the measurement of atmospheric transmission over distances up to about a mile was exhibited in the Photometry Section This instrument is based upon the Maxwellian view principle, and by means of a Lummer Brodhun prism the intensity of the light received from the distant source is matched by that from a lamp in the instrument The matching has been found to depend on the size of the image which is formed in the plane of the eye-ring For reliable measurements, the dimensions of this image should not exceed about ½ mm.

RADIO DEPARTMENT

Much of the work in the Radio Department is devoted to the higher frequency transmissions which have assumed increasing importance of late An instrument for the measurement of field-strengths at frequencies of 30 Mc. per sec and upwards consisted of a supersonic-heterodyne receiver, the amplification of which could be adjusted to a reproducible value by operating with a constant 'thermal noise' in the output circuit. By means of a radiator (also exhibited) giving a calculable field, the receiver could then be calibrated at this setting and adjusted to any desired lower sensitivity by the incorporation of calibrated attenuators or voltage dividers in the amplifier. A direction-finding receiver used in conjunction with a cathode ray oscillograph for giving visual indications of bearing was also shown. This incorporated two separate amplifiers of closely identical characteristics—a condition on which the whole success of the apparatus depends.

Another interesting exhibit in this department was a very light-weight short-wave transmitter which has been developed for meteorological work This apparatus transmits a wave with two modulations, the frequencies of which depend on the atmospheric pressure and temperature respectively, and hence when flown with a sounding balloon this transmitter gives continuous information of changes of these factors on its journey. The complete transmitter weighs only 4½ lb and has reached heights up to 9 miles and distances of more than 100 miles with good reception throughout

METROLOGY DEPARTMENT

A well designed and recently completed air tight chamber for testing mercury barometers was seen in the Metrology Department This provides accommodation for six barometers including a standard and the necessary adjustments for setting each one can be made from outside The pressure can be varied over a wide range and held constant at any value to within ±0 01 mm of mercury by a barostat control

A determination of g by a reversible pendulum has just been completed The pendulum carries two plane parallel surfaces on which it is swung from a fixed knife edge on the supporting pillar an arrangement with which the effective length of the pendulum may be measured with considerably greater accuracy than one in which the pendulum carries knife edges The effect of the elasticity of the pendulum rod and the finite radius of curvature of the knife edge have been investigated in the course of this work

In the Gauge Testing Section a new self contained vertical type of projector for the examination of plaster casts of ring gauges or of plug gauges up to 3 inches in diameter was shown This apparatus is transportable and can be used in a normally lighted room

ENGINEERING DEPARTMENT

The results of an interesting investigation on frettage corrosion that is the corrosion which occurs between two metal surfaces which are generally regarded as being in non rubbing contact were shown in the Engineering Department It has been shown that the phenomenon only occurs when an alternating and microscopically small relative movement between the two surfaces occurs Certain combinations of soft and hard metals especially when lubricated appear to reduce the corrosion effect but so far no combination of surfaces has been found to be immune In the section devoted to the study of lubrication problems the use of ball ball and ball plane contacts has enabled reliable measurements to be made under boundary layer conditions This has been of particular value in the testing of extreme pressure lubricants Tests on water lubricated rubber bearings have shown that the coefficient of friction of a plane cylindrical bearing is considerably lower than that of the more usual fluted type

A new apparatus for studying the load relaxation of model pipe flanges at high temperatures was also seen in this Department This consists of a very rigid frame in which a series assembly of four flanges is compressed by a hydraulic ram The two centre flanges are thus loaded exactly as in practice, and an extensometer fitted to them measures their total compression The whole assembly was surrounded by a furnace which could be heated up to 600° C

METALLURGY DEPARTMENT

The accurate investigation of the iron carbon, iron sulphur and iron nickel systems which is contemplated in the Metallurgy Department has necessitated the production of a regular supply of very pure iron This is now prepared on a routine basis by chemical methods using electrolytic iron as the raw material The chloride is first produced and this is decomposed by steam at a carefully regulated temperature the oxide so formed being washed free from the chlorides of other metals by water The dry oxide is reduced in hydrogen and the metal melted first under slightly oxidizing conditions then in hydrogen, and finally *in vacuo* The final product contains not more than 0 01 per cent of total impurities The melting of iron without contamination has been made possible by the use of the high frequency furnace and the production of crucibles of alumina and magnesia

In this Department there were also two exhibits one showing the automatic control of the rate of temperature change of a furnace and the other showing the automatic plotting of cooling (or heating) curves by the combined use of which the tedium usually associated with the accurate determination of transformation points can be avoided entirely A new gas fired furnace with an improved design of burner was seen in the foundry This will attain temperatures up to 1900 C and has been used for the firing of the refractory vessels mentioned above and also for testing Seger cones as used in the ceramic industry

AERODYNAMICS DEPARTMENT

In the compressed air tunnel of the Aerodynamics Department a large amount of data upon aerodynamic effects at high Reynolds members has been accumulated Measurements which are in progress on model wing sections include determinations of drag of the position of the point of transition from laminar to turbulent flow on the surface and of pressure distribution over the surface It will thus be possible to separate skin friction drag from form drag and with a knowledge of the transition point to compare the results with predictions from modern boundary layer theory

A model of a small airscrew in front of a thick wing was shown in the duplex tunnel This has been used to investigate the point at which the airscrew becomes so small with respect to the wing that its efficiency begins to fall The data so obtained will be of value in the design of large aircraft in which these conditions are most likely to occur The extensive use now being made of kite balloons has stimulated further interest in their stability and a model of a balloon was seen undergoing tests on the whirling arm

FROUDE LABORATORY

In the Yarrow Tank of the Froude Laboratory a tug propelled by twin paddle wheels, towing two barges, was under test Power and speed measurements were automatically recorded and the method of reduction to ship dimensions was explained A model of a high speed hull was demonstrated in the new tank This type of work is of growing importance owing to the increasing use of small speed boats for naval and commercial purposes

In conclusion, a tribute might well be made here to the garden staff, which has created and maintained the pleasant surroundings in which the Laboratory is set and which help to make a visit on such an occasion as this a delight as well as an interest

Field Days at the Rothamsted Experimental Station

TWO important meetings took place at Rothamsted on June 28 and 29. The first was a gathering of Empire agricultural officers on leave in England who were visiting Rothamsted by the joint invitation of the Station and the Imperial Bureau of Soil Science. This has now become a yearly function, and serves the double purpose of enabling Empire agriculturists to meet each other and acquaint themselves with recent work of the Station and the Soil Bureau. There was a full gathering, and no less than fifteen Empire countries were represented. The programme included a tour of the laboratories and field plots and a brief summary of the work of the Station and the Soil Bureau was given by the Director.

The annual field inspection at Rothamsted was held on June 29, when the Right Hon. the Earl of Radnor, chairman of the Lawes Agricultural Trust, presided over a large gathering of friends and supporters of the Station. The guest of honour was the Right Hon. the Earl of Feversham, Parliamentary Secretary to the Ministry of Agriculture and Fisheries.

The morning was devoted to a visit to the famous field experiments: the Park grass plots showing the effects of fertilizers on meadow hay, and Broadbalk with its striking series of wheat plots. Broadbalk, now carrying its ninety-fifth successive crop of wheat, was in first-class order and showed splendid standing crops where complete manuring had been given. Attention was not confined to the classical fields, and this year the guests were conducted over a modern grazing experiment on High Field carried out in co-operation with the Royal Agricultural Society of England. The purpose of this experiment is to evaluate the fertilizing effect of the residues left behind when concentrated feeding stuffs are fed to cattle at pasture. Tenant right valuers at present use the old and well-known tables of Hall and Voelcker in estimating the compensation due to an outgoing tenant arising from the consumption of concentrated foods on grass, and the present experiment will show whether in present conditions they still remain the most suitable basis, and if not, what should be done to replace them.

In his chairman's address, Lord Radnor stressed the importance of the work on soil fertility in which Rothamsted was engaged. With our shrinking cultivated area and the progressive exhaustion of virgin soils overseas a time would soon come when food production from our home soils would be a vital problem. Knowledge gained now and put in a form that farmers could readily use would serve to meet the demands that sooner or later would be made upon our agriculture. To make full use of its opportunities the Station equipment had to be brought completely up to date, and it was hoped to raise a sufficient sum to have this completed by the centenary, which would be celebrated in 1943.

Speaking of the contribution of Rothamsted to agriculture, Lord Feversham acknowledged the assistance that the Ministry of Agriculture had received from the Station in connexion with the Land Fertility Scheme. The recent work carried out in pasture problems had been of great value in this connexion. He had pleasure in announcing that the Government had granted £14,500 to meet half the cost of the new wing to accommodate the Departments of Chemistry and Biology, while plant physiology was to be housed in a separate building. This money was well spent and would undoubtedly give a good return for the outlay. The taxpayer had frequently been called upon in recent years to make contributions to the agricultural industry. There should be no appearance of subsidizing obsolete methods. One of the functions of agricultural research was to ensure that farmers should have at their disposal trustworthy information on which to base efficient production.

Sir John Russell than gave a brief outline of the work of the Station. Agriculture was at present passing through a period of depression; some people were turning to politics and others to economics as a remedy for the present situation, but these fields were outside the scope of the Station's activities. The purpose of the Rothamsted work was to provide sound technical knowledge and put it out to farmers in such a way that costs could be lowered or output increased. The resources of the Station were amplified in two directions. In pure science the Rothamsted work was linked up with investigations in highly specialized fields, with Prof. V. H. Blackman for example in plant physiology, and with Sir William Bragg at the Royal Institution. On the other side, the Station owed much to the co-operation of expert users of agricultural produce. Thus the Institute of Brewing gave valuable help in the study of barley problems, and the experts of the Sugar Commission in the study of the production of sugar beet. Progressive farmers all over Great Britain allowed the Station staff to carry out experiments on their land under conditions of actual agricultural practice.

Processes of Urine Formation*

THE controversies which in the past have characterized the experimental literature on the nature of renal function have resulted in large part from lack of information concerning the composition of urine at different stages of its elaboration within the structural units of the kidney. The discovery that the kidneys of amphibians and of reptiles can be subjected to direct microscopic observation during life indicated that a way of obtaining such information might be found.

Microdissection methods, as developed by Barber, Kite and Chambers, applied to the kidneys of these animals, have made possible the collection of minute specimens of fluid from Bowman's capsule and from various levels of the uriniferous tubules. Quantitative analyses of these specimens show that with

*Substance of the Croonian Lecture delivered by Prof. A. N. Richards, University of Pennsylvania, before the Royal Society on June 30.

respect to every constituent for which an analytical method could be devised, the fluid as separated from blood plasma in the glomerulus has the composition of a protein free plasma filtrate The blood pressure in the capillaries of individual glomeruli has been measured and found to be significantly higher than the colloid osmotic pressure of the plasma Hence the conclusion seems inescapable that the glomerular process in these animals is physical filtration

Analyses of fluid collected from the tubules have shown that the glucose of the glomerular filtrate is restored to the blood during passage through the proximal convolutions that chloride is reabsorbed and reaction is changed from alkaline to acid by the cells of the distal convolutions Reabsorption of water takes place in both sections of the tubule to a greater degree in the distal than in the proximal segment

Reasons for thinking that the conclusions drawn from these experiments with reference to glomerular function in amphibia are applicable to the mammalian kidney have been derived from study of the excretion of the polysaccharide inulin by dogs and rabbits The results show that this substance which after intravenous injection is excreted rapidly and in high concentration in the urine finds access into the urine solely through the glomerulus From the amount of inulin excreted in unit time and its concentration in plasma a minimal rate of glomerular filtration can be calculated Such calculations show that in non diuretic dogs the volume of glomerular filtrate is more than a hundred times as great as the volume of urine elaborated from it and is sufficient to contain all the constituents of urine normally excreted with the exception of those which are formed within the kidney (ammonia and hippuric acid)

The experiments support the view that the excretory function of the kidney is accomplished at the expense of energy derived from the heart that the work which the cells of the kidney perform consists in the selective restoration to the blood against osmotic gradients of those substances loss of which would disturb that constancy of composition of the fluid environment of tissue cells which is essential for survival

Science News a Century Ago

Freshwater Fishes of Great Britain

THE *Athenæum* of July 14 1838 said We must call the attention of our readers to the completion of a very extraordinary publication In No 16 of this journal (published ten years ago) our predecessors announced the commencement of Mrs R Lee's (then Mrs Bowdich) work on *The Freshwater Fishes of Great Britain*, in which the illustrations are not engraved but are coloured facsimiles of the original drawings all executed by the unassisted hand of the biographer of Cuvier all executed too without the slightest relaxation of pains and finish The fish have been in the first place drawn from life immediately on the specimens being taken out of the water This process may account for a greater gaiety and delicacy of colouring in some of the specimens, than are familiar to the eyes of those who may have been used to examine fish some time after their capture A review of the whole work is here impossible , but now that it is completed we ought to commend it to the notice of all who are interested in the subject were it only as a remarkable we believe in England unique evidence of female energy and perseverance

Mrs Sarah Lee nee Wallis was born in 1791 and in 1813 married the African explorer Thomas Edward Bowdich (1791 1824) Five years after his death she married Robert Lee With her first husband she had studied in Paris and at one time been an inmate of Cuvier's house and in 1833 she published her Memoirs of Baron Cuvier In 1854 she received a Civil List pension of £50 She died at Cork in September 1856

Magnetism of Iron Ships

ON July 14 1838 Captain (afterwards Rear Admiral Sir) Francis Beaufort (1774 1857) then hydrographer to the Navy wrote to the Astronomer Royal Airy that the Admiralty wished him to make experiments on compasses in the iron steam vessel *Rainbow* and a week later the Admiralty gave Airy full powers to proceed The experiments were carried out in the basin at Deptford Dockyard during the course of the summer Among his notes on the work Airy recorded On Aug 17th and 18th I measured the intensity of some magnets to be used in the ship for correction It is to be remarked that beside the effect of polar magnetism there was no doubt of the existence of an effect of induced magnetism requiring correction by other induced magnetism and experiments for this were made in the Magnetical Observatory All was ready for trial and on Aug 20th I carried my magnets and iron correctors to Deptford mounted them in their proper places tried the ship and the compass which had been disturbed 50 degrees to the right and 50 degrees to the left was now sensibly correct On Aug 21st I reported this to the Admiralty and on Aug 24th I tried the ship to Gravesend The results of Airy's experiments were published in the *Philosophical Transactions* on April 25 1839 under the title Account of Experiments on Iron built Ships instituted for the purpose of discovering a correction for the deviation of the Compass produced by the iron of the Ships

Sir James Anderson and Steam Waggons

AMONG the many pioneers of steam road carriages was the Scottish baronet Sir James Caleb Anderson (1792 1861) He took out several patents and his water tube boiler for steam carriages was described in the *Mechanics Magazine* of June 16 1838 A month later on July 14 the Editor published a letter from Anderson in the course of which he said I have spent nearly two *apprenticeships* to this undertaking and have unaided by any company expended about £30 000 on my experiments These have never been brought before the public for I did not consider my carriage until the present time equal to the difficulties to be overcome And I now give the measure into the hands of a company *because it is of paramount importance to the country, that locomotion on common roads should be introduced as widely and expeditiously as possible*, which cannot be done individually, otherwise my partner and myself would have worked it for our own benefit

If the public find my steam drag answer, it will but prepare the way for those of greater talent to introduce them Capital can never be wanted for what is really good , and the public are now awakening to the necessity for locomotion on common roads '

University Events

Birmingham —It is announced that the General Electric Co wishes to give £10 000 to endow two scholarships in celebration of the jubilee of the Company In the letter offering the gift, Lord Hirst, chairman of the Company says 'Bearing in mind our intimate connexion with Birmingham which goes back some 40 years as well as the close interest we have always taken in the development of the University of Birmingham we have decided to put at the disposal of your Council a sum of £10 000 for founding two post graduate scholarships in electrical engineering We sincerely hope that this gift may still further strengthen the bonds existing between industry and our Universities in general and between the General Electric Co the City of Birmingham and the University of Birmingham in particular

The Brewers Society has guaranteed funds to provide scholarships of £100 per annum for training graduates who wish to take a course leading to the degree of B Sc in industrial fermentation and a post graduate course in malting and brewing

The Anglo Iranian Oil Co the Asiatic Petroleum Co and the Burmah Oil Co have guaranteed a fund for providing scholarships, of value more than £100 per annum, for students entering the oil industry tenable at the Oil Engineering and Refining Department of the University

The following lecturers have recently been appointed Miss L Phillip in hygiene and physical training, Dr Thelma Mouat in bacteriology, and Dr R W Pohl in electrical engineering

Cambridge The Frank Smart Prizes awarded in connexion with the Natural Sciences Tripos have been gained by J L Crosby, Magdalene (botany) R G Goode Gonville and Caius (zoology), and Miss M R Osborn, Newnham (zoology)

The Harkness scholarship for proficiency in geology including palæontology value £150, has been awarded to W B Harland, Gonville and Caius College who was placed in the first class of Part II, Natural Sciences Tripos

Edinburgh —At a graduation ceremonial on July 1 the degree of D Sc was conferred on the following for the theses indicated Dr B N Desai Importance of Dialysis in the Study of Colloids , Dr A Haddow, 'Studies in the Biology of Cancer', A G MacGregor, The Volcanic History and Petrology of Montserrat, with Observations on Mt Pelé in Martinique', Dr E G V Percival, Studies in the Carbohydrate Field , I A Galloway, Studies on Certain Viruses Pathogenic for Man and Animals"

London —The Earl of Athlone chancellor of the University, will open the new arts building of Queen Mary College on October 12 This new wing, which is being completed at a cost of £50 000, will be available for teaching and research when the new session opens on October 4 next The top floor will be used for the teaching of zoology Queen Mary College is being largely rebuilt and modernized at a total estimated cost of £200,000

St Andrews —For the triennial period 1935–38 the Senatus has awarded two Sykes Gold Medals for D Sc theses of unusual merit The theses are by Dr G J Robertson on 'Walden Inversion in the Sugar Group' (1936), and by Dr Ian Sandeman on "The Mathematical Representation of the Energy Levels of the Spectrum of Hydrogen (1938)

Societies and Academies

Paris

Academy of Sciences, May 16 (*C R*, 206, 1421 1516)

Jules Drach The differential equation of the third order of the elliptic ϑ functions

Henri Deslandres The universal constant of band spectra Attribution of the lines of the band to other causes than the rotation of the molecule

Ernest Esclangon The aurora borealis of May 12 1938 Description of the effects seen in the Paris region the phenomenon was less intense than that observed in England and Germany

Georges Denigès A new reaction of cystine applicable to its estimation and to its detection in urinary calculi and concretions The reaction is based on the liberation of iodine from a solution of iodic acid acidified with hydrochloric acid It is claimed that no other constituents of urinary calculi liberate iodine in this way

Hwa Chung Lee The transformations of Hamiltonian congruences

Charles Ehresmann The analytical arcs of a Cartan space

Léon Pontrjagin The classification of an $(n+1)$ dimensional complex quantity in an n dimensional sphere

Aryeh Dvoretzky The singularities of analytical functions represented by Dirichlet s series

Kyrille Popoff An extension of the idea of the derivative

Vladimir A Kostitzin Natural selection and the transformation of species from the analytical, statistical and biological points of view

Henri Pailloux The equilibrium of membranes

Léopold Escande Indeterminations and multiple solutions in flow through a submerged valve gate Alternating phenomenon

Svetopolk Pivko The interactions of a helix working at a fixed point with a supporting wing

Henri Mémery An index of stability of the solar activity The ratio of the number of sun spots to the frequency is approximately constant varying only between 5 7 and 6 1 over a period of 56 years

Bohuslav Hostinsky The solution of a general problem of the theory of diffusion

Gérard Petiau The proper function of the fundamental operators of Dirac s theory of the electron

Jean Roubaud Valette The nature of the electromagnetic field in limited relativity

Émile Elchardus Study of the surface tension of fused mixtures containing cryolite

Mlle Nine Choucroun and Maurice Arditi The measurement of superficial electric moments in the midst of a liquid

Ouang Te Tchao and Mlle Anne Marie Moulin The state of equilibrium between large ions and the ions produced by X rays in a gas

Mlle Jeanne Brigando The comparative study of some complex bases

Raymond Chevallier and Mlle Suzanne Mathieu The magnetic properties of ferric hydroxide

Louis Néel The paramagnetism of electrons in a rectangular band

Hugo Steinhaus The localization of objects by means of X rays

Jacques Duclaux and **Miguel Amat** Ultra filters of graduated porosity A method based on the solubility of cellulose acetate in aqueous solutions of magnesium perchlorate These solutions coagulate instantaneously in contact with water and give a porous film The concentration of the cellulose acetate determines the porosity

R Gregoire The mass numbers of the stable isotopes of the elements 43 61 85 and 87

Mlle Marie Falinski A basic zirconium sulphate obtained by hydrolysis of the normal sulphates

Michel Lesbre Complex organic compounds of lead

Jean Desmaroux The action of dilute acids on the nitrocelluloses observation of steric hindrance The considerable variations in the hydrolytic action of various acids are due to the fact that the large ions penetrate the nitrocellulose structure with difficulty owing to their size

Marcel Mathieu and **Mlle Thérèse Petitpas** The solubility structure of the denitrated nitrocelluloses

Max Mousseron and **Robert Granger** The monohalogen derivatives of methylcyclohexane

Augustin Boutaric and **Maurice Engeldinger** Dilatometric researches on a synthetic resin

Alfred Silberstein The crystalline structure of some bromocupric compounds

Science and Government

A LECTURE entitled "Science and Government", recently delivered to the Royal Philosophical Society of Glasgow by Prof. J. Graham Kerr, raises questions of the widest concern. Its theme is the utilization of science in the interests of the community and the inculcation of scientific methods of thought into governance – matters outside the sphere of party politics. Prof. Graham Kerr is a believer in democracy and prefers our bureaucratic system to that of totalitarian States; the former is slow in action but flexible, while the latter, though more speedy in action, has a certain rigidity, and its dependence on the ability and principles of the individual renders it liable to a sudden collapse. He compares the bureaucratic machine to an organism. Its increase in size contains its own elements of danger in the development of a longer and longer chain of organization, which is liable to have weak links and thus to break down under strain.

It is unquestioned that the organized modern State depends on the successful applications of science, alike to the feeding, motility, health and recreation of the whole population, as well as in securing the safety of the community from foreign aggression. The development and efficiency of services in these matters are the sole concerns of several ministries. The business of their executive officers is, for the most part, the application of regulations in their different spheres, but secondarily they have to advise the ministers responsible to Parliament. As the higher departmental staffs consist of individuals generally chosen for ability by examinations in which science, being unprofitable, is a subordinate subject, ministers can scarcely rely upon their advice in major concerns; if capable of understanding, they have not the time—perchance, the inclination—to keep abreast of the advances of science. Hence the institution of advisory committees, strongly endorsed by Prof. Graham Kerr on account of their "cold-blooded, judicial consideration" of questions placed before them.

The personnel of these committees, having been properly selected, must subject the ministers to no "fussy interference", while, above all, a ministry must in its turn try neither to persuade nor to bring pressure by raising purely administrative or political difficulties. As a general principle, it is suggested that every administrative ministry, civil and military, should have its own advisory committee, and examples of the success of these committees are given. In all cases where a ministry has its own scientific department, it should help its members to discuss their scientific problems with colleagues whose activities are more concerned with the fundamentals of science. In the modern civilized State, however, all these matters depend ultimately for their success on the general educational system, which is considered by Prof. Graham Kerr to demand a thorough overhaul as a matter of national concern.

Considering the topic 'science and government' more widely, we regret that Prof. Graham Kerr did not let his thoughts wander to the Empire. The Dominions have made considerable advances in education by the evolution of new technique and the development of almost new subjects—and in most of their interests they have independent experts upon whom they can call for advice. The Colonies have practically no experts apart from those commercially and personally concerned. Colonies represent earlier stages in the evolution of civilized States and independent democracies than do Dominions Their environmental conditions are obviously immature Health is all important food has to be produced perhaps new foods introduced transport should be easy luxuries from abroad must be balanced by excess production culminating in exportation and lastly all questions concern at least two races of man in each colony Here as in the home State success depends on experts between them capable of applying each branch of science More often than not these experts are private individuals who risk their wealth in practical business an excellent arrangement provided that this business is kept duly subordinated to the interests of the colony

The executive officers of a colony have to devote their energies to keep the machinery of government smoothly running and to this end have now some training enabling them to consider the interrelationships of races living together How far are these individuals largely chosen for their informative and cultural education capable of dealing (for example) with food production and perchance the reports of specialist officers if they themselves are ignorant of the basal methods employed in such work ? Obviously governors of colonies scarcely belong to the present age but how many of their executive officers have been trained in the methods of science ? What value is placed on such knowledge in their selection ? In the probationary period before proceeding to colonies what time is devoted to training in the scientific method if the individual is chosen for other sides of learning ? In other words have the methods in the governance of the Colonies kept pace with the scientific evolution of the last decades The Colonial Office alone has the information necessary for reply In democracy colonies must be held by the consent and goodwill of the governed and the Empire demands an efficiency of management leading through prosperity to a permanency of union

Lastly from our point of view the payment and pension problem has long been a matter of concern the conditions in the scientific services being inferior to those in the administrative In a statement to Parliament* the Colonial Office appreciates the necessity of a Standardisation of Conditions which since a uniform pension rate has been laid down as suitable for officers of the unified Services can only mean a gradual rectification of a grievance of scientific workers This is a necessary step to secure the best recruits for the scientific services the training for which is long and intensive and in which only men of high ability are required The Colonial Office thereby attains a liberty of action which previously it could not exercise No longer need it transfer an officer who has made an intensive study of the scientific problems of one colony to a post in another thus promoting him while rendering his study nugatory If the Colonial Office requires he can now be called upon without injustice to identify himself with the particular colony in which his success and perhaps affection lie The old system of promotion solely by transference was often unsuited to the scientific services and made permanency in any colony a sign of ineffectiveness

Principles of Factorial Experiments

The Design and Analysis of Factorial Experiments
By F Yates (Imperial Bureau of Soil Science Technical Communication No 35) Pp 96 (Harpenden Imperial Bureau of Soil Science 1937) 5s

THE publications of the various Imperial Bureaux are necessarily of very unequal scientific value and naturally also, appeal to very different bodies of scientific workers Their format and presentation are not such as to excite an expectation of material of wide interest Thus the reader who encounters first in large letters Imperial Bureau of Soil Science and then the somewhat repellent caption Technical Communication No 35 is not well prepared for the exceptional interest of the material presented by Mr Yates in the monograph under notice It should therefore be stated at once that this particular publication has been awaited eagerly by experimenters in all parts of the world and that in providing not only a much needed compendium of well established designs but also the practical solutions of a number of the problems outstanding it will more than justify the expectations that have been formed

For at least a century experimenters have felt the need, and have frequently attempted, to incorporate two or more factors in the same experiment Two of the classical fields at Rothamsted, dating from 1852, are such attempts Unfortunately, they did not know how to reap the great advantages of such arrangements, without incurring even greater drawbacks A long history, involving on one side the experimental exploration of the nature of the experimental errors , on the other, the gradual development of adequate statistical techniques , and, finally, the recognition of the conditions upon which the mathematics could be made applicable to the experimental facts, lay between the aim and its fulfilment It is the knowledge acquired in this long process, and the changes in point of view which this knowledge has induced, that have brought factorial experiments to the fore Designs formerly felt to be extravagant, or dangerously ambitious, are now known to be demonstrably more economical in time and money than any available alternatives They require, however, careful planning and foresight When high precision is aimed at, they may be very intricate Their statistical reduction will defeat the novice who has not studied the subject Only those who feel that this is too high a price to pay for efficiency and comprehensiveness will be tempted to ignore the opportunities which the work of recent years has revealed

Of the seventeen sections, the first is introductory It contains a clear brief statement of the purpose of the memoir The next two sections deal with a three-factor experiment with eight experimental combinations, this useful type serving excellently to illustrate the notation for the recognition of particular components The scheme of progressive sums and differences (p 15) is an especially valuable feature, and will save much tedious calculation

Confounding and partial confounding are introduced in Section 4 with the same example The real advantages of partial confounding, however, only appear in the following section with the discussion of general 2^n designs, that is, of the simultaneous use of n factors at two levels each The reader should note the elegantly balanced sets of confounded components for experiments with thirty-two combinations in blocks of eight, or of four (p 25) A practical example of confounding thirty-two combinations in blocks of eight, shows a gain of more than 48 per cent in the precision of the components conserved Since the loss is only one fifth in the interactions of three or of four factors, even the components partially confounded would in these circumstances have 19 per cent higher precision than without confounding

The treatment of factors at two levels only is completed in Section 8, with a highly original series of designs for confounding in Latin squares This is an idea which considerably influences the later sections In the introduction it is suggested that the loss of precision which, prior to the introduction of confounding, used to accompany the simultaneous testing of large numbers of treatment combinations, was due principally to the necessity of abandoning the Latin square It is therefore of importance that 4 × 4 and 8 × 8 squares can be used very efficiently A wide choice of designs is available, and the section will repay very careful reading

With Section 9 we come to the use of factors at more than two levels The section is excellently planned to give the reader an adequate background for the application to these more complex problems of the many devices already applied to factors tested at two levels only The most difficult sections are devoted to these Especially valuable is the notation for the interactions of a number of factors at three levels, the understanding of which greatly facilitates the appreciation of the later designs

A point of very general interest emerges in the last section The great difficulty of factorial designs, which the previous sections have shown how to overcome, lies in the large number of combinations which need to be compared The technique of confounding and partial confounding, in answering this difficulty, incidentally shows the way to deal with the typical problem of practical plant improvement, where the geneticist is faced with the testing of a host of promising segregates obtained from crossing. In the quasi-factorial designs these are treated *as if* they were the combinations of two or more 'factors , and in this way a large number n of varieties may be tested in blocks of only $n^{1/2}$ or $n^{1/3}$ plots This represents an enormous gain in practical efficiency , won, in this case, at the cost of some complexity in the statistical treatment of the data Triple lattices based on the Latin square ought to be much more widely used when their advantage is appreciated, and when high replication is available the balanced lattices or 'balanced incomplete blocks' provide a type of experiment in which all comparisons are of equal precision (whereas with the unbalanced lattice they are slightly unequal), and the computations are correspondingly simplified

The lattice square is a beautiful application of the same principle using the elimination of rows and columns (Latin square) in place of only the elimination of differences between blocks To compare forty-nine varieties with only four replications in four Latin squares of which the eight subdivisions by rows and columns form a mutually orthogonal set, is an achievement astonishing in its simple ingenuity The last section in fact is all too short and might perhaps have been given space at the expense of Section 16 devoted to split plot designs Every possessor of the monograph at least ought to examine in relation to his own problems the possibilities of this last section

The details of the arithmetical analysis are given throughout so that no experimenter need hesitate to apply even an intricate design if it appears to suit his requirements for fear that the data obtained will prove unmanageable

R A FISHER

Atomic Realism

The Renaissance of Physics
By Dr Karl K Darrow Pp viii + 306 + 17 plates (New York The Macmillan Company 1936) 12*s* 6*d* net

DR DARROW'S capacity for making rough places smooth is well known and is admirably shown in this popular exposition of modern advances in physical science For the most part he has chosen to be guided by the motto which Kamerlingh Onnes proposed for physics *Door meten tot weten* through measuring to knowing — a phrase that carries one back to the fifty year old pronouncement of Kelvin that it is not until you have measured a physical quantity that you can really begin to say you know something about it There is room for very pretty argument in both statements the shape of the earth—sphere spheroid ellipsoid and finally with a gesture of despair geoid—has become more elusive as precision of measurement has increased but that may be let pass for the nonce

It is a fact that a great many popular expositions of modern physics concern themselves more with the presentation and discussion of results than of methods and the inquiring layman thereby loses some entrancing stories of experimental technique and possibly gains some very warped notions of the manner in which the experimenter has arrived at the astonishing conclusions of the last generation Indeed some of the popular expositions leave one with the impression that the subject has just growed and give not an inkling of the experimental methods that lie behind it all Dr Darrow's book is a wholesome corrective of such views He has an eye for the essential in a physical experiment and the intelligent reader will rise from the perusal of this work with some knowledge not only of what has been done but also of how it has been done

It is needless to attempt to define the scope of the book with any fullness of detail It is sufficient to say that waves and corpuscles and the structure of the atom are topics which are discussed at length when and only when the reader has been given a sound grounding in the relevant parts of the elements of classical physics and the grounding is none the less thorough even though the work is almost entirely devoid of mathematics It is significant however that the name of Heisenberg and the terms uncertainty and indeterminacy do not appear in the index

It is with mild regret rather than surprise that one finds Dr Darrow in the ranks of the atom seeers (not *seers* which is another matter) He directs our attention to the observer who marking a luminous trail in the sky says I see a shooting star and makes a parallel between that experience and the experience of him who observing a trail on a photographic plate exclaims I see an atom—or a sub atomic particle Moreover he reminds us that as lately as 1909 a brilliant and distinguished man could print Atoms like molecules are fictions The language of chemists has become so saturated with the phraseology of the atomic and molecular hypotheses that we speak in terms of atoms and molecules as if they were objects of immediate observation It must be reiterated therefore that this language is figurative and is not to be taken literally
Strange words indeed to be published in 1909 and re read in 1936 !

Yes and they may very well be compared with the words of Lord Kelvin written but a few years earlier than 1909 in which he avers his belief in the reality and substantiality of the luminiferous ether The fate of that avowal might well give pause to the enthusiastic atom realists of the nineteen thirties

It does seem that in these matters the man of science is permitting himself to become something of a pseudo philosopher and to confuse the model with the reality Indeed much of the trouble centres on the use and the misuse of the term real If I sum up a number of sense data in the expressions This is a table and This table is *really* solid I am using words in a commonsense way to which I apprehend no metaphysician would take exception But it is a different and much more debatable matter when I proceed to say This table is *really* made up of a cloud of sub atomic particles and for the most part is *really* empty space" We are now, in our use of the word 'really' adventuring into philosophic regions of thought and, though it is perfectly true that we may advance through science into philosophy, it is also true that philosophical studies are as technical in character as physical studies and, lacking that technical knowledge, the man of science may find himself suffering a sea-change into a half-baked metaphysician

Atom, ether, quantum-mechanical model all these dwell in a conceptual world which we build up to imitate, as closely as may be, the happenings in the world of sense-data in which we move and live We perceive some such event as a column of mercury in a barometer tube, the 'slow-decaying oscillations' of a torsionally-suspended disk in air, certain groupings of the weights on a balance pan which record the results of a chemical reaction, and we find that the concept 'atom' in our model world best correlates these happenings in the world of perception The atom does not come one whit nearer reality, using that word in the way originally defined, if we add to our perceptions that of, say, a streak on a photographic plate, or a flash of light on a phosphorescent screen This is not to say that a concept can never become a reality in the perceptual world—some miraculous change in the scale and powers of our being may bring the atom into the region of direct sense-perception, but until that happens, talk of its reality is just irrelevant Moreover, when concept becomes percept, it is more than likely that some other feature will be added to the conceptual model to account for the new set of facts in the world of perception

This considerable digression must, however, not be interpreted as conveying any fundamental criticism of Dr Darrow's delightful book, which is one of the best and most stimulating of the popular reviews of modern physical science that has appeared during recent years

A F

Planning of Social Progress

The Middle Way.
a Study of the Problem of Economic and Social Progress in a Free and Democratic Society By Harold Macmillan Pp ix+382 (London Macmillan and Co, Ltd, 1938) 5s net

THOSE who weary of the puerile aspects of party politics, and think that the 'something rotten' in the State is its economic structure, will welcome this thought-compelling book with its major premise that social changes are ineluctable but amenable to human direction Fully cognizant of the value of co-operation and of public ownership or control of certain essential services, the author lays down some fundamental rules for peaceful progress along a middle road between socialism and capitalism, which should ensure the safety of democracy and lead ultimately to the highest degree of individual freedom compatible with the general good

The first rule is to mitigate poverty and to banish that great scourge of civilization—economic insecurity and the fear of it There must be a minimum standard of living, attainable through a legal minimum wage, higher unemployment benefits, and certain family allowances, and to meet the extra cost of these, industries and services must be made more efficient, a few more of them put under public control, and the whole integrated and rationalized Private enterprise and the free play of competition are desirable in young and expanding industries, but after that stage co-ordination by the industries themselves, with proper safeguards against monopolistic abuses, becomes necessary, and eventually certain key industries are best transferred to public ownership Coal, power, transport, a central bank, investments, foreign trade, and essential foodstuffs (including purchase and distribution of milk and other dairy produce, bread, sugar and potatoes) would all in time come under public control, each being managed by a special board in consultation with and supervised by a national economic council

The above represents but a *coup d'œil* over the vast field covered by this book, which is of remarkable value and free from obvious bias or error (except *grains* for *grams* on page 40). Study of it, however, leaves a doubt whether such reforms would be properly implemented, and if so, how long they would endure, in an acquisitive society ruled largely by individual self-interest Lasting success would seem to demand an enlightened outlook, which might be achieved by drastic changes in educational methods Youth must be served that health and "joy through work" be attained, not by means of mass suggestion, dogma and violence, as in the totalitarian States, but by inculcating freedom of thought and expression, reason and persuasion Economics *and* education are the two vital fronts on which the citadel of human discontents must be attacked E H T

Physical Chemistry of Textile Materials

Kolloidchemische Grundlagen der Textilveredlung
Von Dr Emmerich Valkó Pp xi+701 (Berlin Julius Springer 1937) 60 gold marks

IN this book Dr Valko gives a remarkably comprehensive account of the present position of physico chemical investigation in relation to many aspects of the manufacture of textile materials The title is perhaps not altogether fortunate since the scope of the book is wider than it suggests Moreover the author is well aware that modifications of the physical characteristics of the various textile fibres are *fundamentally* determined by the chemical nature of the sub stances composing them and he also recognizes that nothing is gained by simply labelling obscur ities in behaviour as colloidal phenomena

The first chapter consists of a very useful de scription of the chemical constitution and mole cular and crystalline structure of cellulose wool keratin and silk fibroin It includes an able critical review of the results obtained from attempts to estimate the chain length of cellulose molecules In Chapter iii an interesting account is given of the arrangement of the molecules in cotton wool and other fibres as deduced from their optical and mechanical properties and from their behaviour in the diffraction of X rays the absorption of liquids and in other respects Evidence for the existence of structural units in the form of sub microscopic molecular aggregates (micelles or more specifically crystallites) is presented in a judicious fashion In particular it is emphasized that optical and mechanical anisotropy of the fibre cannot be regarded as direct proof of the presence of crystallites Chapter iv deals with the sorption of water by the fibres and the consequent alteration in their dimensions and mechanical properties The nature of the sorption process is fully discussed in the light of the available informa tion due weight being given to the data obtained in studies of the heat of sorption sorption hysteresis and the specific volume of the fibres

Chapter v is devoted to the consideration of the chemical and physical behaviour of wool and silk when treated with solutions of acids and bases and Chapter vii deals with various aspects of the mercerization of cotton While clearly explaining how the principles of the Donnan membrane equilibrium may be operative in the swelling of wool silk and cellulose the author is careful to indicate the limitations of the osmotic theory In reviewing work on the absorption of alkali by cellulose Dr Valkó appears to have overlooked an investigation by Hibbert and co workers (1930) which provides further evidence in favour of chemical combination in equal stoichiometric proportions The degeneration and activation of cellulose and the modification of wool by the action of chlorine and other reagents are con sidered at length in Chapters viii and ix Short chapters on the morphology and histology of fibres the electrokinetic behaviour of cellulose and the felting of wool complete the first half of the book

The next three chapters which occupy about a third of the book deal with the nature of aqueous dispersions of dyes the principles underlying dye ing processes and the behaviour of dyes when fixed on the fibres They form a particularly valuable feature of the book since the need for a summary of this kind has long existed It is frequently supposed that in the direct dyeing of cotton the dye is held in virtue of its colloidal condition Dr Valko shows that while this view is not supported by the results of recent work with purified dyes there is reason for postu lating an *indirect* connexion between the colloidal character of the dyes and their dyeing properties in the sense that the forces which produce associa tion of the dye molecules in solution are also responsible for their attachment to the fibre

An excellent account is given in Chapter xiv of the properties (including surface tension) of solutions of soaps using this term in its widest sense Recent developments in this field are described in detail since they are of special interest in regard to the elucidation of the state of the soap at the concentrations employed in textile practice In the following chapter interfacial phenomena and the stabilization of emulsions and suspensions are discussed in connexion with the wetting wash ing and impregnation of the fibres The greater part of the remaining chapter is allotted to the physical chemistry of starch solutions there being in addition short sections on gum arabic methyl cellulose and the processes of sizing and printing

The author designedly excludes consideration of purely mechanical processes and processes involved in the actual formation of artificial fibres Within the limits imposed however little of importance appears to have escaped mention Certainly full justice is done to the work of British investigators

The book should facilitate collaboration between specialists in the industries concerned and prove stimulating to all interested in colloid chemistry Though packed with information it is very readable as Dr Valkó maintains a lucid and agreeable style throughout The diagrams are very numerous and the book is well produced T R BOLAM

Historic Haunts of England

By Gwen Woodcock Pp xiii+368+48 plates (London Alexander Maclehose and Co, 1938) 7s 6d net

IN the phrasing of a bygone age, Mrs Woodcock combines instruction with entertainment In this companion to her volume on Scotland she has selected more than fifty places of interest scattered throughout England and has given her readers a bird's eye view of the salient features of the history of each Topographical and architectural details are strictly subordinated to elucidating the story This is told admirably in a graphic and succinct narrative without unnecessary ornament The author's interest is catholic, and she covers not only picturesque towns, such as Dover and Rye, Burford Beverley or York, but also castles great houses, such as Knole and Hatfield, and ruins and prehistoric monuments, Kenilworth, Avebury and Stonehenge Illustration is generous and excellent

Lest a necessarily brief account of a book containing much, but not an overload of detail, should convey the impression that it is no more than an excellent 'gossiping guide, it may be pointed out that from the author's judicious selection of incident and the frequent juxtaposition of a number of distinct narratives of events drawn from identical periods in time, certain general trends in the history of the English people emerge Such are for example the forces which welded the English a people of so diverse an origin, into one, or the development in the relations of nobles and people and the cognate matter of the divergencies in form and character of the English township and the origin of these divergencies, some towns being appanages of a great house such as Arundel and Warwick, others groupings of independent burgesses arising with the early growth of trade, commerce and industry as do the towns of the Cotswolds or the Cinque Ports which base their independence on the sea

(1) Wild Flowers in Britain

By Robert Gathorne Hardy (British Nature Library) Pp 120+104 plates (London B T Batsford Ltd, 1938) 8s 6d net

(2) Everyman's Wild Flowers and Trees

Five Hundred of the British Wild Flowers, Trees, Shrubs, Grasses, and Ferns, described and illustrated, 384 in colour after Sowerby's "British Wild Flowers", and 120 from line drawings by the Author By Miles Hadfield Pp vii+184+32 plates (London J M Dent and Sons, Ltd, 1938) 6s net

DURING the past few years there has been a spate of illustrated guides (not necessarily floras) to the plant life of Great Britain, especially the flowering plants Some have been scarcely anything but vehicles for artists' impressions of attractive flowers, while others have proved very helpful not only to the amateur naturalist but also to the professional botanist Now, therefore, in any new work on British wild flowers, we may feel justified in demanding some distinguishing features to warrant its publication

(1) In Mr Gathorne Hardy's book we see such features His ultimate aim is to instruct the amateur in the pleasures rather than the science of botany and he would be a very hardened reader who does not become captivated by the author's pleasing style of description He writes with such literary prowess and enthusiasm for his subject that the book makes good armchair reading Thus it might fail in its main purpose but it would be failure along the right lines because the book is so beautifully illustrated The photographs (many of them full page) are some of the best we have seen They have clearly been chosen with care from the work of the best living Nature photographers Mr John Nash's colour lithographs make an enchanting decoration to the whole work Botanists and all other Nature lovers should welcome this book as a distinctive addition to a subject rather over burdened in books

(2) Mr Miles Hadfield's book comes under a different category since instead of putting the beauty of plant life in his book he puts the layman reader in the way of finding it in Nature for himself The illustrations are useful for identification purposes only, but that was obviously intended The author's main aim is to extend the scope of the book to deal not only with herbs but also with trees, shrubs and ferns by omitting the rarer species which only the skilled botanist is likely to recognize The book opens with descriptions of classification and naming of plants, the structure of leaves and flowers, and means of identification This is followed by illustrated descriptions of five hundred plants, grouped in families A distinctive feature of the work is the consideration of the economic value of certain plants, garden relations and the meanings of the botanical names of plants The author is to be congratulated on the production of a really useful book

Clowes and Coleman's Quantitative Chemical Analysis

an Intermediate Text Book Edited and revised by Dr D Stockdale and J Dexter Fourteenth edition Pp xiv+617 (London J and A Churchill Ltd 1938) 18s

IN this new edition of a well known text book the type has been completely reset and a large part of the text rewritten Additions include accounts of the gravimetric and volumetric determination of aluminium and magnesium by 8 hydroxyquinoline, the colorimetric determination of aluminium, the use of the chromate radical in the determination of barium, lead and sulphates, ferrous phenanthroline as an internal redox indicator, a brief introduction to the use of ceric sulphate, and the analysis of cupro nickel by salicylaldoxime The book thus includes some well tried modern methods of analysis

The sections on the analysis of water, foods, oils and fats, and gas analysis have been retained, since although these subjects are now best dealt with in special treatises, the processes included provide very useful introductions for the senior student, and also enable the teacher to set alternative exercises in special cases The book is a thoroughly sound and accurate one and its continued popularity may be predicted

Vāgbhata's Aṣṭāngahṛdayasaṃhitā

ein Altindisches Lehrbuch der Heilkunde Aus dem Sanskrit ins deutsche ubertragen mit Einleitung, Anmerkungen und Indices Von Dr Luise Hilgenberg und Prof Willibald Kirfel Lieferung 1 Pp iv+64, Lieferung 2 Pp 65–128, Lieferung 3 Pp 129 192, Lieferung 4 Pp 193 256 (Leiden E J Brill, Ltd , 1937) 3 50 guilders each part

OF the early Indian treatises on medicine, that of Vāgbhata is one of the most important The author flourished at the end of the eighth century, A D , and although translations of his works have appeared, he seems to have remained to a large extent unrecognized and unknown He divides his matter into sections In Part 1, theoretical principles are considered, based upon the conception that The chyle, blood, flesh, fat, marrow and sperm are the seven bodily elements that may become corrupted Towards the end of this section, various surgical instruments are described and pictured—forceps, bone and lion forceps, straight and curved needles, saws, and others—all much like those used at present Certain surgical procedures are also described, such as methods for the removal of foreign bodies from wounds Part 2 deals with the physiology of the body, commencing with conception, pregnancy and birth, and Part 3 with the etiology of disease, discussing fever, coughs, respiratory affections and heart disease consumption and urinary troubles, abscesses and abdominal complaints

The translation appears to be a scholarly one, an attempt is made to convey the exact meaning of the original, and in order that there shall be no doubt the Sanskrit word is frequently given in brackets after its German equivalent Further, the various plants, etc , comprised in Vāgbhata s materia medica are identified so far as possible We await with interest the completion of the work

Aristotle

Parts of Animals , with an English translation by Dr A L Peck , Movement of Animals , Progression of Animals , with an English translation by Prof E S Forster (Loeb Classical Library, No 323) Pp v+556 (London William Heinemann, Ltd , Cambridge, Mass , Harvard University Press, 1937) 10s net

HERE is the Greek text, faced by excellent translations, of the three works of Aristotle of most interest to students in animal physiology, namely, Parts of Animals , Movement of Animals and Progression of Animals Dr Marshall s Foreword" sets the right key for the reader, namely, composition leading to function, first tissues consolidated into organs Aristotle is altogether charming , his method is that of science—and students and the dilettanti, who read, will be delighted The food of plants ' is already concocted before it enters them, and in return for it they yield their fruit and seeds" Horns on the head offer the least possible hindrance to the movements of the body in general "The Progression of Animals is quite a basal treatise for research, so popular to day, on the swimming and other movements of animals

The Sturge Collection

an Illustrated Selection of Foreign Stone Implements bequeathed in 1919 by William Allen Sturge By Reginald A Smith Pp viii+131+plates12 16 (London British Museum, 1937) 21s net

THIS volume, dealing with stone implements from foreign sites, completes the publication by the British Museum of the Sturge Bequest, the vast collection of stone implements bequeathed to the nation by Dr Allen Sturge, who died on March 27, 1919 The first volume by Mr Reginald Smith dealt with implements from sites in Britain , and in the volume now issued the same authority has selected a representative sample of the remaining implements Of these the greater number come from France, but other sites represented are in the various countries of Europe Asia Minor Egypt Africa north, east west and south, Palestine, India, the Far East and Australia The American section is regarded as ethnographical, and has been omitted

As the basis of a scientific investigation, the collection suffers, according to the modern orientation of archæological studies, from lack of adequate documentation , but as a whole the assemblage of so vast a collection of specimens representative in type, is in itself of immense value Its use is facilitated by the succinct but admirable explanatory paragraphs which Mr Smith has prefixed to the descriptive notes on each group of specimens selected for illustration, these being arranged under sites on a geographical basis of distribution, taking Britain as its starting point The references to the more important literary sources for each site are in valuable as an *aide memoire*, as well as a guide

An alphabetical list of sites represented in the collection also serves as an index

Qualitative Inorganic Analysis

By A J Berry Pp viii+147 (Cambridge At the University Press, 1938) 6s

PERHAPS the main features of this book which distinguish it from many other excellent text books on qualitative analysis are (1) the inclusion of several so called rare elements (such as thallium, zirconium, vanadium and lithium) which are now less expensive and are also of scientific and technical interest, and (2) the inclusion of many modern reagents (particularly organic compounds) in the descriptions of the reactions of the radicals

After a short but commendably clear and instructive theoretical introduction, the book deals fully with the reactions of the metals in the order of the usual groups, with the reactions of acid radicals, with the systematic analysis of the metals, and with the examination for acid radicals The author does not approve of the use of analytical tables, so he omits them , many teachers will wish that they had been included The directions for group separations are, however, quite clear, and the disadvantages of turning over pages and getting more of the book stained by reagents may be outweighed by some advantages which are not very clear to the reviewer

Antarctica and Glacial Ages

By Prof. E. W. MacBride, F.R.S.

THE effects and causes of glacial ages have been discussed from many points of view—'observational and theoretical—and the meteorological aspects of the problem were very clearly presented by Sir George Simpson in his Royal Institution discourse published as a Supplement to NATURE of April 2 What is said in the present article may be regarded as complementary to Sir George's survey of the subject, the point of view being that of a zoologist and palæontologist instead of meteorologist or astronomer In the collection of the facts embodied in the article, I have had the advantage of help generously afforded me by Dr Stephenson, geologist attached to the Graham Land Expedition, and by Prof W W Watts

If we desire to know what a glacial age was really like, the obvious course is to study a part of the world where such an age is still in existence Greenland and Antarctica are two such regions, but Antarctica is preferable to Greenland because it is of continental size Antarctica is roughly circular in outline and has a diameter of 3,000 miles Its area thus works out at about 7,000,000 square miles The maximum height of the continent is 3,168 metres or about 10,000 feet This is situated about 200 miles north of the south pole

The whole continent is covered with a huge ice-sheet through which only the highest peaks protrude as two volcanic cones, Mounts Erebus and Terror The part so far principally studied is that directly south of South America, in which lies the inlet known as the Ross Sea The length of the ice-sheet known as the Beardmore Glacier flowing into the Ross Sea is about two hundred miles, but it joins the great barrier ice-shelf which extends several hundred miles farther out to sea and from the outer edge of which great tabular icebergs are constantly being cut off If we add the breadth of the ice-shelf to the length of the Beardmore Glacier, we arrive at a total extent of ice-flow of about five hundred miles, and this is considerably longer than any glacier the existence of which we have evidence in the Pleistocene Glacial Age From the evidence of erratics carried on the glacier, Dr Stephenson has been able to make a rough guess as to the nature of the geological formations buried beneath it. Rocks of the Gondwana age, with coal-seams carrying characteristic fern plants, are present the Gondwana age is usually described as Permo-Carboniferous Beneath it are folded schists of the Pre-Cambrian or Huronian age

Now, rocks of Gondwana age with the same characteristic fossil plants are found also in the Deccan of India, in South Africa, and South America, and it is evident that all four areas formed parts of a southern continent for which the name of Gondwanaland has been adopted. It is clear that this continent during the early part of the Gondwana age enjoyed a mild climate and hence must have been situated a considerable distance from the pole, but later it underwent a severe glaciation known as the Gondwana ice-age. Antarctica, however, which formed part of this continent, entirely escaped this glaciation We conclude, therefore, that during this period the continent must have drifted across the south pole but that Antarctica, which formed part of its northern edge, escaped this glaciation. The drift then must have originated to the south of Australia, and as Australia itself formed part of Gondwanaland, the drift must have begun after the breaking off of Australia from the rest

The point which we wish to emphasize is that this -the greatest ice-age of which we have evidence—was not due to the chilling of the atmosphere or of the sea but solely to the high latitudes into which Gondwanaland drifted Long ago Tyndall pointed out that to describe a glacial age as an age of cold was an entire misconception, for, he said, if we calculated the energy necessary to evaporate the enormous masses of ice embodied in the ice-sheets from the sea we should describe a glacial age as a period of greater heat—not cold What makes a glacial ice-sheet is the condition that in some part of the earth more snow should fall in winter than can be melted in the following summer For this condition to be fulfilled not only must there be intense local winter cold but also an abundant supply of atmospheric moisture. These conditions can be well studied in Canada in which I had the good fortune to live for twelve years In Montreal the average winter snowfall was six feet on the level. drifts up to depths of fourteen feet were common It was an ordinary experience to travel on ski or Indian snowshoes over the tops of buried fences. The ground under this snow-sheet was practically unfrozen. In contrast to Montreal the snowfall at Winnipeg was less than a foot and the ground beneath was frozen to a great depth and to this circumstance Winnipeg owed its magnificent wheat crops As the spring began the surface layer of the soil melted and the wheat grains pushed their radicles into this layer As the sun grew stronger the wheat roots grew longer and everywhere they encountered a reserve of water in the freshly melted ice of the soil

How narrow was the margin which separated Eastern Canada from the inception of a new ice age may be gathered by the following observations which were made by me During the whole of one August the back gardens of many Montreal houses were encumbered by vast masses of unmelted snow Now the first snow of the winter is expected on November 1 and considerably before that period there are hard ground frosts at night Even in September nights frosts occur so that if in this particular autumn these frosts had been a little more continuous a considerable portion of the August snow drifts would have survived into the winter and thus the formation of a new ice sheet would have been begun

Up to about 1880 the Pleistocene glacial age was the only one of which we had any geological evidence When at last the conviction was forced on geologists that there had been a severe ice age in Permo Carboniferous times the usual result followed there was a wild scamper on the part of enthusiastic pioneers to find ice ages in all periods of the world s history Such ages were discovered in Cambrian Ordovician Silurian Jurassic and Cretaceous times and a fearful mess was made of glacial chronology The pioneers always forgot that the ultimate cause of ice ages was not the chilling of the atmosphere but greater evaporation from the sea As the movement of an ice sheet produces a mixture of thick clay with large stones which easily becomes a conglomerate with lapse of time it was easy to suggest a glacial origin for all the conglomerates which recur in the stratified series If however glacial ages are due to the drift of land into high latitudes then this drift must be somehow the result of the rotation of the earth and must follow an orderly course we cannot at will ferry lands over sea and back again in order to satisfy our theories

There seems however to be a consensus of geological opinion that there was a Pre Cambrian ice age The best evidence for this in fact the only indubitable evidence is found in Canada In the Temiskaming region of Northern Ontario where the Huronian strata have been exploited for the world famous silver mines of Cobalt a conglomerate with large boulders has been found But these boulders when extracted from the mother rock are found to have smooth surfaces marked by parallel striæ exactly like those found on boulders in the Pleistocene boulder clay or for that matter in the moraines of recent glaciers Their glacial origin is therefore definitely proved Other records of Huronian strata from other parts of Canada showing evidence of ice action are almost certainly fragments of the same deposit

That there has been a northerly drift of secondary rocks since Permian times is shown by Old and New Red Sandstone beds of Europe and eastern Canada The red colour of these sandstones is due to grains of laterite but laterite is a degradation product of granite and is only found in tropical regions At the present day its formation is going on amongst the granite hills of Nigeria

Whilst the Gondwana ice age was raging in the south contemporary beds in Spitsbergen show evidence of a warm tropical climate There are beds of coal with fossil plants showing evidence of a rich tropical flora

We have seen that drift into high latitudes affords a complete explanation of all glacial phenomena previous to the Pleistocene When however we approach the consideration of the pleistocene glacial age we find that this explanation is no longer applicable The Pleistocene glacial deposits are represented both in the northern and the southern hemispheres and were therefore contemporaneous all over the world Further in the Pleistocene glacial ages alone do we find evidence of long continued interruptions of glacial activity During these interruptions stratified beds were laid down containing plants bones and shells bearing testimony to a comparatively mild climate There seem to have been at least four periods of intense cold separated by milder inter glacial periods The cold periods were named by Penck the Gunz the Mindel the Reiss and the Wurm The most interesting thing about these periods is that the bones and tools of the oldest indubitably human race are found in the interglacial interval between the Wurm and the Reiss periods

Since the Pleistocene ice period was world wide its cause must be sought outside the south in the sun If as we have already stated the primary cause of these periods is an increase in evaporation from the sea there must have been increased radiation from the sun Now some of the irregularly recurrent phenomena of the sun are sun spots These are solar cyclones of enormous dimensions and are associated with intense radiation They are connected with the well known magnetic storms and with displays of aurora borealis If then during a period extending over several million years there were frequently repeated increases in solar radiation, we should have increases in evaporation from the sea and consequent increases in precipitation in the colder regions of the earth The interglacial periods would be associated with few sunspots and reduced evaporation and precipitation During them the glaciers would gradually shrink, exposing great masses of boulder clay which would be washed away by the melting ice and deposited as thin bands of sand and clay elsewhere Visitors to Switzerland who have noted the milk-white appearance of the Upper Rhone during the summer months will need no further reminder of the nature of the water issuing from the foot of a melting glacier

Coleman, in his book ('Ice Ages"), mentions the continental drift theory but withholds his assent on the ground of the colossal forces necessarily assumed, which he holds to be incredible But, as Sir Thomas Holland has pointed out, there is no possible escape from the conclusion that the tearing asunder of primitive continents and their drifting apart really did take place Actually Greenland has been caught in the very act of drifting A Danish observer, Oersted, has measured the change in longitude of a station in the extreme south of Greenland between the years 1922 and 1932 The amount determined was 600 feet, that is, 60 feet a year If we calculate back 100,000 years, we find that Greenland must have then been lying close to Norway Now from observations on the annual layers of silt deposited every summer by the streams fed by the melting ice, it has been ascertained that it is about 13,000 years since an ice-sheet covered the whole of Sweden The great Wurmian glaciation may have lasted 100,000 years to judge from the enormous extent of the boulder clay which it produced On the west coast of Wales the clay and boulders carried by this ice-sheet which had crossed the Irish Sea were piled up to a depth of 200 feet A period of 120,000 years would carry us back into the interglacial period between the Reiss and the Wurm glaciations—the time indeed when Neanderthal man flourished

When the exposed boulder clay became dried out it broke up into dust, and this under the name of 'loess' was blown about by the wind In central China this loess is piled up to a depth of hundreds of feet A similar degradation of soil into dust is taking place in North America

We must conclude with a few words about the bearing of these climatic changes on evolution. What changes the Pre-Cambrian ice-epoch produced in life we do not know, but the researches of Prof D M S Watson and Dr R Broom on mammals prove that the growth of cold-blooded reptiles into warm-blooded mammals began directly after the Gondwana ice-age During the Miocene epoch a continuous forest stretched across the Old World from the shores of France to the coast of China Bones and skulls show that this forest was inhabited by the higher apes, the direct precursors of man , but in Pliocene times a northern drift of the old Africa and the Deccan of India began which, impinging on the tableland of central Asia, raised up the enormous barriers of the Himalayas and associated mountains and in Europe the Alpine chain

Thus the ape population was cut into a northern and a southern group the latter continued to find its living in the forest, where remnants of it persist as the chimpanzees, gorillas, orangs and gibbons of to-day The northern group, however, had to face a more severe climate, the first beginning, in fact, of the Pleistocene ice-age The forest gave way to steppe and the apes had to change their habits to hunting on the ground, and primitive hunting man was born

Thus there would be much truth in the epigram . the Gondwana ice-age produced the warm-blooded mammals, the Pleistocene ice-age produced man.

The Organization of Knowledge

THE unprecedented progress of science and its applications during the last hundred years has given rise to a flood of literature, the magnitude of which has dulled our senses into a sort of acquiescence About two thousand new volumes on scientific subjects are issued annually by British publishers, while the number of scientific papers published in a year throughout the world has been estimated to amount to three quarters of a million. A century ago, a scientific worker was expected and able to digest for himself practically the whole of the original literature of his subject. To-day it is with difficulty that he can keep abreast of a particular part of it, even with the aid of a new type of abstracting and indexing literature, which has been evolved specially for this purpose. If he would seek to know what discoveries, which might be useful to him, have been recorded in other branches of his own and different sciences, he must depend entirely upon such services

The need for the evolution of this new kind of library *aide memoire* is now universally recognized. Indeed, a terrifying sense of insufficient mental material is beginning to dawn upon the minds of a few individuals, particularly of those whose special interest lies in the domain of the applications of science to the benefit of mankind. For that is not knowledge which we do not know where to find. Nevertheless the present deficiencies and lack of organization in this new research service seem in danger of being overlooked, and the necessity of assembling and perfecting this mechanism of knowledge is not realized, although, perhaps, as much as fifty per cent of modern technical research could be saved if complete information as to recorded data could be made available.

We need to realize, as Mr. Maynard Keynes has expressed it, that "we do not even know what is to be known", and straightway to set about in earnest to organize a master key to the vast storehouse of recorded information. This is not a question of merely making bibliographies, but of providing a complete bibliographical service, so that anyone can ascertain immediately exactly what information has been recorded on every new question as it arises.

It was for the purpose of the solution of this important problem that the International Institute of Bibliography was founded by an international conference in Brussels in 1895. To this end the Institute has worked for more than forty years. The data concerning the problem have been ascertained, principles have been evolved, much progress has been made—progress which increases year by year. National sections of the Institute have been founded in many countries. The Institute has sought, with growing success, to link together all those—both institutions and individuals—whose interest lies in the collection, classification and dissemination of information. Last year at a World Congress on Documentation, held in Paris by invitation of the French Government, and attended by representatives of thirty Governments and forty international organizations, the Institute was recognized unanimously as the controlling international bibliographical organization, its federative character being expressed in the decision to change its name to International Federation for Documentation.

At this meeting it was decided to hold in England the Fourteenth International Conference of the International Federation for Documentation.

The British Government has extended its patronage, and Sir William Bragg, president of the Royal Society, has accepted the presidency. The chairman of the organizing committee is Dr. S. C. Bradford. The Conference will be held at Lady Margaret Hall, Oxford, on September 21–25, followed by final sessions at the Science Museum, South Kensington, S.W.7, on September 26. Advantage of the meeting being in England has been taken to include joint sessions with the annual conference of the Association of Special Libraries and Information Bureaux. Eminent representatives of every branch of intellectual activity have given their support to the Conference. Papers will be read by leading authorities from many countries. Successful as has been the work of the International Federation in the past, it has tended rather to confine itself to making more easily available the literature relative to the natural sciences and their applications. Opportunity will be taken of the forthcoming Conference to endeavour to secure greater collaboration with bibliographers in other fields, such as those of history, archive work and economics. Special attention to these subjects will be given in the papers to be read.

Among the hundred or more papers which have been offered to the Conference we notice the following: Grundsatzliches zur Frage der Vereinheitlichung und Normung auf dem Gebiete des chemischen Referatenwesens, by Dr. Maximilian Pflucke, chief editor of the *Chemisches Zentralblatt*; Bibliographical tools from the user's point of view, by Dr. J. Holmstrom; Le travail bibliographique internationale dans les domaines des études historiques, by P. Carron, director of the Archives de France; Archives in their relation to other forms of documentation, by Hilary Jenkinson, secretary of the Public Records Office; On the present state of documentation in Switzerland, by W. Janicki, past president of the Swiss National Section of the International Federation for Documentation; and The current German situation in the field of practical documentation, by Dr. A. Predeek, chief librarian of the Technische Hochschule, Berlin.

The titles of the papers to be communicated, together with full information concerning the Conference, are given in the preliminary programme, a copy of which can be obtained on application to the secretary, Miss M. Gosset, Science Library, Science Museum, South Kensington, S.W.7. The programme includes visits to some of the many interesting places in the neighbourhood of Oxford, together with other social functions, such as receptions by the Vice-Chancellor and the Mayor, and a Government banquet in the beautiful hall of Christ Church.

All who appreciate the vital importance of the organization of information will realize that the visit of this Conference to England provides a special opportunity of assisting in the discussion and development of a service which feeds the roots of intellectual progress.

Whales and Whaling

International Conference

UNTIL some ten years ago, modern whaling was conducted almost entirely from land stations, and the most important centres of the industry were in British territorial waters where suitable regulations could be enforced The development of the modern factory ship led to a great expansion of the industry in the form of unrestricted whaling on the high seas, and the operations extended over a vast area in the Antarctic The Governments of those nations most interested in whaling realized that unlimited hunting must eventually cause depletion of the stock and the collapse of the industry An International Conference was therefore held in June 1937, and an agreement was signed by representatives of the Union of South Africa, the United States of America, the Argentine, Australia, Germany, the United Kingdom, the Irish Free State, New Zealand and Norway By the terms of this agreement, measures were taken for the restriction of whaling, including the imposition of a minimum size limit for various species, the limitation of the Antarctic whaling season to three months, and, with minor reservations, the prohibition of pelagic whaling north of 40° S

In accordance with the recommendations of last year's Conference, a second Conference was held on June 14–24 last. The purpose of this Conference was to invite the adherence of other countries which had not yet acceded to the previous convention, to examine the results of the new regulations and to consider what further measures might be applied The following Governments sent delegates: Union of South Africa, United States of America, Argentine, Australia, Canada, Denmark, Eire, France, Germany, United Kingdom, Japan, New Zealand and Norway An observer also attended on behalf of the Portuguese Government, and the interests of Newfoundland were watched by the United Kingdom delegation

The Conference noted that although the provisions of the 1937 agreement had limited the scope of Antarctic whaling, it had not succeeded in checking the number of whales killed Indeed it appears that the number of whales taken in the 1937–38 season was approximately 44,000, which is about 10,000 in excess of the figures for the previous season This is partly attributable perhaps to the high price of whale oil last year. Had it not been for the agreement of 1937, a still larger number of whales would no doubt have been taken.

The new measures agreed to in this year's Conference are embodied in a protocol which amends the existing agreement, and the discussions and recommendations of the Conference are reported upon in a final Act The following are among the articles in the protocol

Factory ships are prohibited from taking Humpback whales anywhere south of 40° S for a period of a year There is evidence that the stock of Humpbacks stands in even greater danger than that of Blue whales, and the Conference considered a proposal for the world-wide protection of this species for a year Agreement to this could not be reached, since many land stations are largely dependent on Humpbacks Protection in Antarctic waters, however, is expected to save large numbers

Pelagic whaling is now totally prohibited in the Pacific sector of the Antarctic, south of 40° S. and between 70° W and 160° W This applies in the first instance for a period of two years Although whaling has not so far spread to these waters, it is known that the number of whales there is sufficient to be worth protecting Practical difficulties militate against the imposition of such a sanctuary in the established whaling grounds, but the new measure may at least act as a check on future expansion

The open season of three months in the Antarctic remains unchanged, as do the minimum size limits for the various species, but small concessions in size limits have been made for land stations where the whale meat is used as food for local consumption

The other articles of the protocol include a clearer definition of a land station (a point which provoked much discussion over the status of factory ships working in territorial waters) and minor amendments to some articles in the principal agreement

The Conference considered a resolution of the Whaling Committee of the International Council for the Exploration of the Sea in the following terms "The Committee, viewing with alarm the evident decline of the stock of Blue whales, is of opinion that nothing less than limitation of the total amount of whale oil which may be taken in any whaling season can be effective in preserving the stock of the whales from being reduced to the level at which it can no longer be the object of economic exploitation" It was felt, however, that at the present stage it would be impossible to reach agreement to such a measure which would involve fixing a global quota each year and arranging to cease all whaling when the quota was reached

Proposals for limiting the number of catchers attached to each expedition and for limiting the oil production of each factory ship were also abandoned on account of the difficulty of apportioning such restrictions equitably among the various expeditions

It will be seen then that the new measures agreed upon do not go very far but the first object of the Conference which was to secure the prolongation of the existing agreement and the adhesion of additional Governments has been achieved The principal agreement has been ratified by the Governments of Eire Germany Norway New Zealand United Kingdom and United States of America whilst Canada and Mexico have since acceded to it The Argentine is enforcing the principal agreement by executive decree and formal ratification is only a matter of time It is understood that ratification by Australia and South Africa has been delayed only by constitutional difficulties and the accession of France and Denmark is expected to follow The Japanese delegation informed the Conference that its Government was prepared to take steps to accede after the interval of a year and to observe the principles of the agreement as nearly as possible in the meantime This undertaking of the Japanese is regarded as of great importance since that nation is now operating on a large and increasing scale in the Antarctic

In the final Act it is recommended among other things that the Governments and the whaling enterprises concerned should do their best to encourage the development of whale marking as practised by the Discovery Committee

The question of holding a future conference is recommended for consideration in the light of developments N A M

Obituary Notices

Dr W W Campbell For Mem R S

By the death on June 14 of W W Campbell following that of G E Hale American science has suffered the loss of another astronomer who was also a foreign member of the Royal Society

William Wallace Campbell was born and bred on a farm in Ohio the date of his birth being 1862 He graduated in the University of Michigan in 1886 and the soundness of the academic training which he had then received is sufficiently attested by the nature of his later career A year or two were then spent as professor of mathematics in the University of Colorado after which he returned to the University of Michigan as instructor in astronomy In 1891 Campbell joined the Lick Observatory as astronomer The rest of his active life was connected for forty years with that institution and with the University of California Retirement came in 1930 and before his death he had made his home in San Francisco

Campbell became acting director of the Observatory on the death of Keeler and the appointment was definitely confirmed in the following year (1901) He had in an eminent degree that combination of qualities which is necessary for success in the head of a great observatory in an isolated situation and in this capacity he had the valuable support of his wife Elizabeth Ballard Thompson whom he married in 1892 There were three sons of this marriage all surviving He was also fortunate in finding a problem peculiarly adapted to his powers Keeler before turning to his classical researches on the nebulæ had pushed the study of the radial velocity of the brightest stars as far as was practicable by visual means Further progress required the introduction of photographic methods The circumstances on Mount Hamilton were exceptionally favourable but the technical problems involved in avoiding the effects of flexure and maintaining uniform temperature had to be solved by original devices Campbell developed great skill in dealing with the optical and mechanical problems thus presented and in the Mills spectrograph he achieved a classical design Chiefly by this instrument in conjunction with the Lick refractor the radial velocities of all the brighter stars within the reach of the Observatory were determined with high accuracy in the course of a few years To complete this new chapter in astronomy by extending the work to the whole sky an expedition was equipped and established at Santiago in Chile The effectiveness of this branch from its beginning at first under the leadership of Mr W H Wright is a proof that the success of Campbell's plans was by no means dependent on the famous Lick telescope

The Lick Observatory though it possesses a splendid equipment is generously maintained as a department of the State university but it has no endowment For all the expenses of the branch in Chile and the cost of additional instruments as the need arose Campbell had to rely largely on the generosity of wealthy friends of the Observatory among whom the late Mr D O Mills and Mr W H Crocker may be specially mentioned His conspicuous tact and persuasive qualities were clearly shown in gaining this necessary financial support

Eclipse expeditions occupied much of Campbell's time and thought In all he took part in seven

India (1898), Georgia (1900), Spain (1905), Flint Island (1908), Kiev (1914), Washington (1918) and West Australia (1922), where he obtained results confirming the theoretical value of the Einstein effect Apart from this, Campbell's main contribution was to the study of the flash spectrum by means of a spectrograph provided with a slit and moving plate, by which the height of the exciting elements in the reversing layer could be accurately recorded His preparations for an eclipse expedition were a model of organization

So conspicuous were these powers of organization and administration that Campbell was persuaded in 1923 to become president of the University of California a position which he retained until 1930 without giving up the control of the Lick Observatory These were years of notable expansion in the University, which is now perhaps the largest in the world having more than 15,000 students resident at Berkeley and a total enrolment with other local centres exceeding 24,000 After retirement from the University and from the direction of the Observatory in 1930 Campbell became president of the National Academy of Sciences (1931 35)

Campbell's astronomical writings will be found for the most part in the publications of the Lick Observatory His Elements of Practical Astronomy (1899) is an unpretentious work, which many students must have found useful His 'Stellar Motions , which was published in 1913, brings together in an attractive form that part of astronomy to which his own researches had made so large and important a contribution

In addition to numerous academic honours, Campbell received the gold medal of the Royal Astronomical Society in 1906, both the Lalande and the Janssen Medals from the Paris Academy of Sciences and the Bruce Medal in 1915 As president of the International Union of Astronomy in 1922 25, he presided over the Cambridge meeting of that body In the same year, 1925, he delivered the Halley Lecture at Oxford

The opening years of the present century witnessed a notable expansion in the methods and outlook of astronomy In this development Campbell played an outstanding part His character was energetic and forceful, and his successful career can be attributed to a perfect harmony between his considerable powers and the researches which the circumstances of the time led him to undertake An English fellow in the Lick Observatory cannot fail to add a tribute to his unfailing kindness, and the practical help which he was always ready to give His sense of duty was outstanding When, after recovering from the serious illness which brought his services to the University of California to an end, he became president of the National Academy of Sciences, he might have looked forward to an honourable period of comparative leisure at Washington But it was not to be The condition of national affairs led the Government to appeal to the Academy for help in a great variety of problems In dealing with these Campbell did not spare himself, with the result that these years of office, so far from bringing dignified ease, were perhaps even more strenuous than any in his busy life In him has passed away not only a great astronomer whose name will remain in the history of the science but also one who was no less conspicuous in the public service of his country H C P

Dr Alexander Galt

DR ALEXANDER GALT whose death at the age of eighty three years occurred on June 26, was appointed keeper of the Technological Department, the Royal Scottish Museum Edinburgh in 1901, the year in which the Department was founded He graduated at the University of Glasgow where he was a Thomson (Lord Kelvin) scholar in physical science, and a Donaldson scholar in natural science For eight years he was official assistant to Lord Kelvin in Glasgow University Among his publications were papers on physics and physical chemistry in the *Proceedings* and *Transactions* of the Royal Societies of London and Edinburgh He was external Examiner in Experimental Physics for degrees in Arts and Science in the University of Edinburgh in 1910–14

Soon after the Royal Scottish Museum came under the control of the Scottish Education Department, the new post of keeper of the Department of Technology was offered to Dr Galt The inauguration of this Department was really a reversion to the original purpose of the Museum founded in 1854 under the name of the "Industrial Museum of Scotland' Dr Galt had no previous experience of museum work, although he had the important qualifications of a large educational experience, a scientific training and a wide and intimate knowledge of science and its application to industry

While the work of organizing the Department was one of exceptional difficulty, it offered great opportunities to Dr Galt's creative abilities After careful study of the problem it was decided to illustrate, by means of models and specimens the great industries of general engineering coal mining, and the manufacture of iron and steel Other branches of science and industry were added later and the scope of the collections was extended

Under Dr Galt's personal supervision many very fine working models of engineering mining, and other interest were constructed in the Museum workshops, and added to the growing collections, which are to day of world wide repute

Miss Edith Stoney

THE British Federation of University Women has suffered a great loss in the death, on June 25, at the age of sixty nine years, of Miss Edith Stoney who, on the day of her death, had been elected one of its vice presidents Edith Stoney was a member of a distinguished Irish family of scientific workers , her father, an uncle and a brother all being fellows of the Royal Society, whilst her sister, Dr Florence Stoney, was one of the pioneers of X ray work in medicine

Edith herself was a mathematical physicist As a student of Newnham College in 1890–94 she took both parts of the Mathematical Tripos, being bracketed equal to the seventeenth wrangler in Part I She also had charge of the telescope at Newnham After leaving Cambridge she became head of the Physics Department in the London (Royal Free Hospital) School of Medicine for Women, a post which she resigned in 1915 to take up war work She joined the Scottish Women's Hospitals and served first in the Tent Hospital at Troyes where she put up and ran the X ray Department, and afterwards in Serbia, where the unit was ordered by the French authorities Later she became lecturer in physics at the King's College for Household and Social Science

Edith Stoney travelled considerably, and a visit to Australia convinced her of the need for visits from Great Britain to the Dominions She supported these views practically and generously by her gifts to the British Federation of University Women of research studentships in science to enable younger women graduates of the universities of Great Britain and Ireland, who were also members of the Federation, to go to these countries She was so pleased with the success of her first scholars in Australia and New Zealand that this year she gave a sixth studentship, this time to be held in South Africa, to which the award was made at a meeting attended by Miss Stoney only a week before she died The subjects of the studentships awarded included biochemistry, zoology (insect parasites) and botany It is learned that in her will she has left money to the Federation for the continuance of these Johnstone and Florence Stoney Studentships Her association with the Federation has been a great stimulus and pleasure to her fellow members, who will be deeply sensible of the loss they have sustained in her death

Prof. Rudolf Vondráček

By the death of Prof R Vondráček at Brno on June 12, Czechoslovakia has lost a distinguished chemist and technologist Vondráček began his career as a research worker in pure and applied chemistry whilst completing his studies under Prof Votoček at Prague, with whom he investigated the separation of certain reducing sugars by hydrazine Altogether he contributed about fifty original papers to Central European periodicals and he was the author of four text books

After a period spent in the laboratories of industrial concerns and during which his researches related mainly to analytical methods, Vondráček spent some time before and during the Great War as an examiner for the Austrian Patent Office in Vienna In December 1918 he returned to Czechoslovakia to take up the appointment as professor of chemistry at the Brno Polytechnic, a post he held until his death During this time he was twice dean (1920–21 and 1930–31) and he filled the office of rector during the session 1935–36

His most important researches are connected with a study of the corrosion of metals and with the chemistry and physics of fuel technology He made careful investigations into the calorific value of various fuels and directed attention to certain anomalies in fuel analysis such as the variation in the estimated water content, an apparently greater loss being recorded at 100° C than at 105° C He noticed, too, a 'time lag' in the absorption of moisture by coal

Prof Vondráček was an authority on the destructive distillation of fuels at low temperature, for the experimental study of which he used a bath of boiling sulphur He carried out analyses of the gases evolved by the Czechoslovak petroleum springs at Gbely and succeeded in removing carbon monoxide and unsaturated hydrocarbons from the gas which is used locally for lighting and heating Even his physico chemical researches had some bearing upon industrial technology Thus, almost his last work was a study of the binary systems of phenol with hydrocarbons He found among other things, that phenol is a suitable reagent for the separation of hydrocarbon mixtures being preferable to such means as nitration or bromination

He was a member of many continental scientific societies and was prominent in the activities of the Masaryk Academy of Work G D

Mr A W Shorter

We regret to record the death of Mr A W Shorter, assistant keeper in the Department of Egyptian and Assyrian Antiquities of the British Museum (Bloomsbury), which took place on May 31 at the age of thirty two years

Alan Wynn Shorter was the son of Mr Wilfrid Wynn Shorter, and was educated at St Paul's School and Queen's College, Oxford where he graduated in 1928 Before taking his degree he had for some time devoted himself to the study of Egyptology and more especially to the study of the religious beliefs and rituals of the ancient Egyptians, as set forth in The Book of the Dead On leaving Oxford in 1928 9 he spent a year working on the excavations of the Egypt Exploration Society at Tell el Amarna, and on his return to England he secured an appointment on the staff of the British Museum Here in the Department of Egyptian Antiquities he was able to continue his study of the material culture, arts and religion of the ancient Egyptian people He was the author of a number of popular books on these subjects, and also contributed to the publications of learned societies, specializing in the study of Egyptian papyri His principal contribution to Egyptology is a 'Catalogue of Egyptian Religious Papyri in the British Museum"

We regret to announce the following deaths

Prof R M Bird, professor of organic chemistry in the University of Virginia, on June 4, aged seventy one years

Dr B T Galloway, formerly pathologist in the U S Bureau of Plant Industry, on June 13, aged seventy four years

Sir Colin Mackenzie, formerly director of the Australian Institute of Anatomy, aged sixty one years

Mr H N Thompson, C M G, lately director of forests, Nigeria, on July 9

News and Views

R. L. Hobson, C.B.

MR. ROBERT LOCKHART HOBSON, keeper of the Department of Oriental Antiquities and Ethnography of the British Museum (Bloomsbury), will retire on July 20. Mr. Hobson, who was educated at St. John's, Leatherhead, and Trinity College, Cambridge, taking a first class in the Classical Tripos in 1893, joined the staff of the British Museum in 1897, when he was attached to the Department of British and Medieval Antiquities and Ethnography. Specializing in the study of ceramics, his early published work dealt with English pottery and porcelain, but later he directed his attention to the ceramics of the Far East, on which he became one of the first authorities in Great Britain, especially in the broader cultural aspects of the subject. His "Chinese Pottery and Porcelain" (1915) was followed by a number of volumes of both special and general interest, such as "The Wares of the Ming Dynasty" (1923), "The Art of the Chinese Potter" (1923) and "The Later Ceramic Wares of China" (1925), but his most considerable production was his authoritative "Catalogue of the Eumorfopoulos Collection" (1925–28). He was also the author of the official guide to the collections of Far Eastern pottery in the British Museum (1924). Mr. Hobson became deputy keeper of his Department in 1921, and on its reorganization some years later as the Department of Oriental Antiquities and Ethnography, was appointed keeper. He received the honour of C.B. in 1931.

Prof. R. V. Wheeler

PROF. R. V. WHEELER has been awarded the Melchett Medal for the current year of the Institute of Fuel. Prof. Wheeler will give the Melchett Lecture to the Institute at 3.30 p.m. on October 13, in the meeting room of the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1. Non-members of the Institute who desire to be present at this meeting will be welcome. Prof. Wheeler has been for many years professor of fuel technology in the University of Sheffield. He is also the director of the Safety in Mines Research Board Experimental Stations in Sheffield and Buxton. Born in 1883, he was educated at Plymouth College, Plymouth, and Owens College, Manchester. He is a Dalton scholar and fellow of the University of Manchester. He is the author or joint author of many publications dealing with the constitution of coal, blast furnace coke, coal mining problems, scientific and technical papers on coal combustion and flame, besides being joint editor of *Fuel in Science and Practice*.

Pilgrim Trust Lectures

IN the annual report last year of the Royal Society, it was announced that the Pilgrim Trust had agreed to provide 250 guineas a year for six years for an annual lecture to be arranged jointly by the Royal Society and the U.S. National Academy of Sciences, and to be delivered alternately in London and Washington. It is now announced that the first Pilgrim Trust Lecture will be delivered in London on December 8, and the Royal Society has selected Dr. Irving Langmuir, a director of the Research Laboratory of the General Electric Company, Schenectady, as lecturer. The second lecture is to be delivered on April 24 of next year and the National Academy of Sciences, to which falls the task of selecting an Englishman as lecturer, has chosen Sir William Bragg. As Sir William emphasized in referring to the Lectures in his presidential address to the Royal Society last November, they present a unique opportunity for direct interchange of thought by leading men of science of the two countries, and the selection of Sir William to give the first lecture in the United States is both a well-deserved compliment and a gesture signifying approval of the views which he has expressed as to the functions of these lectures.

South African Protectorates and Transfer

A DEPUTATION representing the Committee on Applied Anthropology of the Royal Anthropological Institute has been received by Mr. Malcolm MacDonald, H.M. Secretary of State for the Dominions, in order to discuss the question of the consultation of native opinion with regard to the transfer of the Territories to the Union Government of South Africa. The deputation was introduced by Lord Onslow, who (as reported in *Man* of July) referred to the difficulty experienced by the Joint Select Committee on Closer Union in East Africa in understanding the point of view of native witnesses who appeared before it. A variety of points was discussed. Both Prof. B. Malinowski and Dr. Margaret Read, who have recently visited the territories, were in a position to emphasize the deep interest taken by the native population in this question. The latter indeed said that the subject was a matter of discussion so far north as Nyasaland while judging from her own consultations of native opinion, she urged that the traditionally recognized channels for ascertaining the opinion of the tribes should be utilized. This matter was also stressed by the Rev. E. W. Smith, who pointed out that as regards the Basuto a recognized organ for the expression of native opinion existed in the National Council, adding that their land was the matter on which they felt most deeply. Another matter of extreme importance which was mentioned by Dr. Margaret Read was the care that should be taken in the interpretation into native language of terms referring to political institutions. Mr. MacDonald assured the deputation that these points would be kept in mind in putting the issue before native opinion.

Protection of the Aborigines of Australia

THE series of three articles by Dr Donald F Thomson, reciting his experiences among the aborigines of Arnhem Land which appeared in *The Times* of July 5–7, will have been followed with close attention by all who desire a wider application of scientific methods in the approach to the problems arising out of the contacts of Western civilization and peoples of backward culture. A preliminary account of Dr Thomson's work appeared earlier and was noted in NATURE of January 8 (p 68). Dr Thomson, as he himself expresses it, was 'loaned' by the University of Melbourne to the Government of the Commonwealth of Australia to visit, establish friendly relations, and make an anthropological survey of the native tribes, who had been responsible for unrest and trouble in Arnhem Land in 1933. His expedition, as is now well known and as he records, was completely successful in getting into touch with tribes reputed unapproachable, and as a result of his investigations lasting over the two years 1935–37, he was able to present to the Federal Government a report in which he, as an anthropologist, suggested certain measures to be taken if this interesting and, in their way, attractive people were to be saved from degradation and extinction. That extinction is their inevitable fate, unless immediate steps for their protection are taken, is patent from Dr Thomson's alarming discovery that the number of aborigines in these tribes has fallen lower by far than was thought. Further, he was able to point to the grave injury which is being inflicted on the aborigines by well-meaning but mistaken philanthropy. A people who had established an equilibrium in the technique of existence in a country of difficult conditions are abandoning their traditional mode of life to obtain the inadequate benefits of a weekly ration and a few of the cast-off rags of civilization, to their irretrievable detriment.

DR THOMSON suggests as the immediate need of the situation the complete segregation of the aborigines on an inviolable reserve. The aboriginal reserves are in theory already 'out of bounds' for the white population, but in practice this has not been observed. He is also of the opinion that control of all aborigines should be handed over by the State Governments to the single control of the Federal Government. Dr Thomson was able recently to explain his suggestions in fuller detail than was possible in *The Times* before the Committee on Applied Anthropology of the Royal Anthropological Institute (as reported in *Man* of July). After analysing the causes of depopulation and alluding to the failure of missionary effort to turn the tribesmen into gardeners, he went on to suggest that the policy of complete segregation should be supplemented by a legal code adapted to native conceptions, the creation of a special native affairs service staffed by anthropologists, working as mobile patrols, and additional medical service. Further, that the system of segregation should be maintained until a constructive development policy has been worked out for those aborigines who are already detribalized.

An Expedition to North Rona

A SMALL expedition left the Summer Isles by Fishery Cruiser *Vigilant* for North Rona on July 11. Dr and Mrs F Fraser Darling of Tanera expect to spend six months studying the social behaviour and environmental influences on behaviour of the Atlantic or Grey seal, *Halichœrus gryphus*. Dr Fraser Darling has already published researches on the social life found in the red deer and in several species of birds. His work on the Grey seal began with a four months expedition to the Treshnish Isles in 1937. The gregariousness apparent in these seals is of patriarchal type and entirely different from the matriarchy of the deer herds and the communities of pairs which constitute breeding flocks of birds. Dr Fraser Darling's expedition is a private venture, but the cost is being defrayed in part by a fellowship from the Carnegie Trust and grants in aid from the Royal Society, the British Association, the Institute for the Study of Animal Behaviour and the Challenger Society. The Fishery Board for Scotland has co-operated generously in the all-important matter of transport. North Rona lies fifty miles north east of the Butt of Lewis and is a rock-bound islet of less than half a square mile in area. The Atlantic seal repairs there to breed in large numbers from September to November, and the island is also one of the few breeding places of that interesting nocturnal bird, Leach's fork-tailed petrel.

Engineers and International Affairs

IN his address to the North East Coast Institution of Engineers and Shipbuilders, when he received the diploma of honorary fellowship of the Institution on June 24, Rear Admiral G H Rock, of the Constructive Branch of the United States Navy, made special reference to the education of engineers and the participation of engineering organizations in international affairs. In educational circles in the United States, there has been an astonishing increase in the interest in such matters. All the leading nations, he said, are exporters and importers of education in its various forms. There are about 8,500 foreign students in the colleges and universities in the United States and an even larger number of American students are studying abroad. In the academic year 1936–37, 204 American professors were either studying or teaching in foreign universities, while at the same time in American colleges and universities there were 175 foreign professors. No professions are more concerned with international activities than those of shipbuilding and ship operation, and he suggested that institutions such as the North East Coast Institution should lend encouragement to the improvement in the education of naval architects and marine engineers, encourage successful professional men to assist actively in teaching, make more suitable arrangements for ensuring young engineers more reasonable opportunity for employment, and arrange for a more general exchange of students between Great Britain and the United States. Admiral Rock recalled that he received a part of his education in 1890–92 at the University of Glasgow, and he was then sometimes bewildered by leading articles in the *Glasgow Herald* which criticized the enrolment of foreign students in naval architecture and marine engineering. International co-operation, however, he considers, offers more of gain than of loss, in fact, gain for all with loss to none.

The Zeppelin Centenary

By the issue of commemorative stamps, the opening of a museum at Friedrichshafen and in other ways, Germany has been paying homage to the memory of Count Ferdinand Zeppelin of airship fame, the centenary of whose birth occurred on July 8. Born on the shores of Lake Constance, Count Zeppelin was educated at Stuttgart and at twenty years of age became an infantry officer. His military studies led him to visit Italy, France and England, and in 1863 he served with the Union forces in the American Civil War, in the course of his service making a balloon ascent. Returning home he took part in the war between Prussia and Austria and in the Franco-Prussian War and afterwards rose to high command. In 1891 he retired as a general. He had long conceived the idea of aerial navigation by airship, and free from official duties and possessing considerable means, he devoted all his energies to the construction of a rigid airship. In 1900 he achieved his first success with *Z1*, a craft 420 ft. long and 38½ ft. in diameter, the envelope of which contained seventeen gasbags with a total capacity of about 400,000 cub. ft. of hydrogen. The two cars suspended beneath the ship had two 18 horse-power Daimler engines. On July 2, 1900, the airship was hauled out of its floating shed on Lake Constance and covered a distance of 3½ miles before being landed on the water and towed back to the shed. As a military officer, Zeppelin had visualized the use of airships for observations and for carrying dispatches, but their use as a means of transport was his chief aim, and one of his ambitions was to see Europe and America connected by an airship service. This, however, he did not live to see, for he died in Berlin on March 8, 1917, in the midst of the Great War.

Auguste Forel and Alcoholism

In a paper on Auguste Forel and his campaign against alcoholism, read before the Society for the Study of Inebriety and Drug Addiction on July 12, Dr. J. D. Rolleston, after a short sketch of Forel's life, stated that though an active campaign against alcoholism had previously been carried out for many years in Great Britain and the United States, Forel was a pioneer in the scientific anti-alcoholic movement not only in Switzerland, his fatherland, but also on the continent of Europe. The lack of recognition of his work in Great Britain was attributed by Dr. Rolleston to two reasons. In the first place, Forel was strongly opposed to making the campaign against alcoholism inseparable from religion and Christianity in particular, as it is in this country and the United States. The second reason was the severe blow to Anglo-Saxon prudery and obscurantism caused by his classical work on the sexual question. On the other hand, the high appreciation of his work in foreign countries was shown by quotation of the opinions of eminent neurologists, psychiatrists and others in Germany, Hungary, Switzerland and the United States. Forel's contributions to the study of the alcohol problem were then considered under the headings of blastophthoria, alcoholism and the sexual question, exposure of popular errors concerning alcohol, such as the view that beer and wine do not cause alcoholism and the value of alcohol as a food, drug, and indispensable agent in sociability, alcohol and sport, and the treatment of alcoholism.

Inland Water Survey

Definite quantitative results of the Inland Water Survey Committee's investigations are forthcoming in the Surface Water Year Book of Great Britain 1935–36 (London: His Majesty's Stationery Office, 5s. net) which is a statistical report (issued by the Ministry of Health and the Scottish Office) relating to the inland water resources of Great Britain during the twelve months ended September 30, 1936. The publication provides detailed information about the surface water resources of a dozen drainage basins, together with their rainfall. Results for underground water are being published separately in a different form. Twenty-seven rivers at twenty-eight gauging stations have been the subject of continuous measurement and the results are tabulated in regard to daily maximum and minimum water levels and daily mean discharge in cusecs. The Year Book furnishes, moreover, in each case a brief description of the station and the drainage area, together with monthly evaluations of rainfall. The issue of this publication, which is to be continued annually, marks a further stage in the development of the Survey and it will be welcomed by all the various bodies who are interested in the use and application of water, whether for agricultural purposes, or for land drainage, fisheries, industries, navigation, sewage disposal or water supplies and the like. Some useful conversion tables are included.

The Norman Lockyer Observatory

The annual report of the Norman Lockyer Observatory, Sidmouth, shows that the activities of the Observatory are well maintained. The 12-in. McClean telescope has been used for taking spectra of ζ Aurigæ during its 1937 eclipse and also of Finsler's comet and of *A* type stars. Its chief work has been in preparation for colour temperature observations on early type stars, and the preliminary experiments have shown that colour temperature observations may be profitably taken up with this instrument. The 9-in. Kensington telescope has been used on a selected number of bright line stars, with special attention to γ Cassiopeiæ. Some photographs of star fields have been taken with the Zeiss triplet camera attached to the instrument. Three meteor cameras fixed outside the dome have been used for the photography of meteors, but unfortunately without success up to the present. Prof. Blumbach has used the Mond equatorial for photographs of galactic clusters, Finsler's Comet, and some test plates of the

Andromeda nebula Two photographs of the aurora of January 25, 1938, were taken by Mr D R Barber, who also contributed notes on its appearance to the local Press The director Mr D L Edwards, supplies many other interesting items in his report, dealing with publications, the laboratory, the library, buildings and grounds, etc

THE Observatory has recently issued the first of a series of bulletins, which will be published from time to time, probably averaging about one a year These will include articles less technical in character than the usual papers which appear in the *Monthly Notices of the Royal Astronomical Society*, and will describe special lines of research undertaken at the Observatory In the present number, the first paper, by Mr D L Edwards, deals with the spectra of γ Cassiopeiæ of which the late Dr W J S Lockyer gave an account a few years ago Considerable changes have taken place since, strong absorption lines replacing the early hazy ones, these absorption lines fading out again and new emission lines appearing The most striking stage was when the absorption lines had completely disappeared and there remained only the spectrum composed entirely of emission lines, the Balmer series of hydrogen being the most prominent feature Prof F I Blumbach contributes a paper which contains six photographs of Comet Finsler (1937 *f*), taken in August and this is followed by Mr D R Barber s paper, Note on the Spectrum of Comet Finsler (1937 *f*) which describes the objective prism spectrograms of this comet, secured on five favourable occasions in July and August A useful table is given which supplies a list of the identified emission features of the cometary spectrum, together with their probable origin, wave length and observed band limits In the next paper, by Mr Edwards, there is a description of a tube sensitometer made to a given specification by Messrs Casella and Co , Ltd , who are also constructing a microphotometer for the Observatory

Popular Astronomy at Mount Wilson Observatory

RECENTLY, the Carnegie Institution of Washington has catered in a practical way for the immense growth of public interest in astronomical research by opening a special building on Mt Wilson to be devoted entirely to satisfying the layman's thirst for first hand information on the many researches undertaken by the staff at Mt Wilson and other astronomers For many years, visitors have been privileged on one night per week to use the 60 in telescope for visual observations of the heavenly bodies, but since the completion of the Angeles Crest highway about two years ago, the number of visitors has become a difficult problem During 1936, it was estimated that 50,000 persons inspected the 100 in telescope when it was open to the public, and the total number who visited the Observatory on all occasions during that year reached the large figure of 100,000 The main features of the building are, first, a room for the display of models and photographic transparencies and, second, a lecture hall, capable of accommodating 270 persons, in which the general public are brought into direct and personal touch with the scientific staff of the Observatory The Carnegie Institution and the Mt Wilson astronomers are to be congratulated on their enlightened policy of giving to the public such unique facilities for the practical understanding of what scientific research is accomplishing in the realm of astronomy

Petrology of Igneous Rocks

WRITING with reference to the review of Hatch and Wells' Petrology of Igneous Rocks ', which appeared in NATURE of May 28, p 952, Dr A K Wells has directed attention to the second paragraph, which he believes suggests that he has been guilty of plagiarizing the scheme of classification of rocks put forward in the report of a research committee of the British Association This was not the intention of the reviewer, who states that at no time has he entertained such an idea He adds that considerations of space precluded mention of the fact, well known to him and to others interested, that Dr Wells was the moving spirit of the committee in question The main object of the review was to indicate the radical changes made in the new edition of Hatch and Wells well known text book

White Fish Commission

THE Minister of Agriculture and Fisheries and the Secretary of State for Scotland have appointed the following to be members of the White Fish Commission constituted under Part I of the Sea Fish Industry Act, 1938 Sir William Palin Elderton (chairman), Mr H G Maurice (vice chairman) Prof Alexander Gray, Mr G Dallas, Mr T Darling The Commission is charged under the Act with the functions of keeping generally under review matters relating to the white fish industry, and of advising and assisting the Ministers in regard thereto The Secretary of the Commission is Mr R G R Wall, to whom all communications should be addressed at the Offices of the Commission, Nos 6 and 7 Old Palace Yard, Westminster, S W 1

Weather Forecasts by Telephone

IN *The Times* of July 11, there is an account of a new enterprise on the part of the Dutch meteorological service and Dutch General Post Office In Great Britain, anyone can get the latest official weather report over the telephone by asking for it at the Meteorological Office, but on the Hague telephone system the subscriber need only call the number 393131 and he will hear automatically the latest forecast, not only for Holland, but also for Great Britain, Belgium and North and West Germany To this is added a statement of the distribution of high and low barometric pressure over Western Europe, and doubtless also an indication of the way in which the distribution is changing

British Empire Cancer Campaign

ON the recommendations of its various committees, the Grand Council of the British Empire Cancer Campaign has made the following grants, totalling

£3,715, which are in addition to the sum of approximately £45,000 already approved in grants for the calendar year 1938. £1,100 to the Radium Beam Therapy Research, £750 for research by Mr F C Pybus at Newcastle, £300 to Dr P. R Peacock, at the Glasgow Royal Cancer Hospital, for the salary of a whole time assistant, £495 for the salary of the physicist at the Strangeways Research Laboratory, Cambridge, £750 for investigations being carried out under the direction of Dr P M F Bishop and Mr H. J. B. Atkins, at Guy's Hospital, £270 to Dr John Bruce, at the University of Edinburgh for part time investigations, and £50 for a replacement in apparatus at the Strangeways Research Laboratory

THE re-appointment of Dr G Cranston Fairchild as the William Morris Research fellow in radiology at Mount Vernon Hospital has been approved for a further period of three years This fellowship was created by the Campaign in 1931 at the request of Lord Nuffield, who provided a sum of £25,000 for the purpose of promoting research work and study concerning the treatment and cure of cancer by radiology

Excavations at Lachish, 1937-38

AN exhibition of antiquities from Lachish, excavated at Tell Duweir, Palestine, by the Wellcome Marston Archæological Research Expedition to the Near East, was opened at the Wellcome Research Institution, 183-193 Euston Road, London, N W 1, on July 7 and will remain open daily from 11 a m. until 5 p m. until July 29 Films of the excavations will be shown daily at 11 30 a m and 3 p m A lantern lecture on "New Discoveries at Lachish" will be delivered by Mr. C H Inge, who has succeeded the late Mr. J. L Starkey as leader of the expedition, on Tuesday, July 19, at 5 30 p m, and on Wednesday, July 27, at 6 p m., admission being free without ticket.

International Congress for Applied Mechanics

THE fifth International Congress for Applied Mechanics will be held at the Massachusetts Institute of Technology on September 12 16, under the presidency of Prof. Karl T Compton At the close of the Congress in Cambridge the members will proceed to Washington, D C, where a programme of sightseeing and visits to Government laboratories will be arranged by the director of the National Bureau of Standards for September 19 Members will then proceed to Langley Field, Virginia (Old Point Comfort) to spend September 20 at the Langley Memorial Laboratory of the National Advisory Committee for Aeronautics. It is probable that other trips will be arranged for those members from abroad who may desire to visit Pittsburgh, Detroit, Niagara, Schenectady and other cities. The field of applied mechanics will be divided into the following general heads: (1) structures, elasticity, plasticity, fatigue, strength theory, crystal structure, (2) hydro- and aerodynamics, gas dynamics, hydraulics, meteorology, water waves, heat transfer; (3) dynamics of solids, vibration and sound, friction and lubrication, wear and seizure Further information can be obtained from the Joint Secretaries, Fifth International Congress for Applied Mechanics, Massachusetts Institute of Technology, Cambridge, Massachusetts, U S A.

Congress of Anthropology and Ethnology

THE International Congress of Anthropological and Ethnological Sciences which is being held in Copenhagen on July 31 August 6, promises an interesting programme While sufficient time is being allowed for giving the various sectional papers, a number of excursions have been arranged For example, a general meeting of the Congress is to be held in the Great Hall of the Castle of Kronborg, where native Greenlanders will show their skill in kayak paddling, etc The most important function of those international congresses undoubtedly is to enable *savants* from different countries to meet and talk together, too many sectional papers leave not enough time for this There are to be the usual number of banquets provided by the various official bodies After the close of the Congress an excursion has been arranged to visit the various places of historical interest in Denmark While one cannot expect to be repeated the outstanding generosity of the Rumanian Government, which last year provided *gratis* for the Congress of the International Institute of Anthropology a sleeping car train for a week to visit all the interesting places in Rumania the total expenses of a member of the forthcoming Congress in Denmark, when everything is considered, will not be at all excessive.

1851 Exhibition Scholarship Awards

THE Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 announces the following appointments for 1938 for research at the various centres indicated *Senior Studentships* Dr W. E van Heyningen, biochemistry at the University of Cambridge, Dr H Walke, nuclear physics at the University of Liverpool, R. Brown, plant physiology at the Imperial College, Dr W A Deer, petrology at the Universities of Manchester and Cambridge, Dr R A Buckingham mathematical physics at the Queen's University of Belfast and the Massachusetts Institute of Technology *Overseas Scholarships* Canada Dr W M Smith, physical chemistry at the University of Cambridge, Dr G C Butler, biochemistry at University College Hospital, London, Dr H J Bernstein, physical chemistry at the University of Copenhagen or the California Institute of Technology; D C. MacPhail, engineering at the University of Cambridge. Australia: A. A. Townsend, physics at the University of Cambridge; A J Birch, organic chemistry at the University of Oxford; M. E. Griffiths, endocrinology at McGill University, Montreal. New Zealand: E F. Daly, physical chemistry at University College, London, or the University of Manchester India: Dr. R. S. Krishnan, physics at the University of Cambridge; Dr. N. K. Panikkar, zoology at the Marine Biological Laboratory, Plymouth.

Travelling Fellowships in Tuberculosis

THE Medical Research Council announces that Dorothy Temple Cross Research Fellowships have been awarded to the following candidates intending to study problems of tuberculosis at centres abroad, during the academic year 1938–39 N C Oswald chief clinical assistant, Brompton Hospital, London J I Paterson second assistant, Medical Professorial Unit St Bartholomew s Hospital, London Dr K M A Perry, medical first assistant and registrar London Hospital, Dr J O Westwater, formerly assistant medical officer, Glenlomond Sanatorium Kinross All these fellows propose to work at centres in the United States

Record Endurance Flight by Glider

Lieut W B Murray and J S Sproule, flying a two seater Falcon glider have set up a record for endurance by remaining in the air for 22 hours 13 minutes, from 4 9 a m on July 9 until 2 22 a m on July 10 The flight was made at the opening of the National Gliding Contests at Dunstable Downs and in difficult weather conditions

Recent Large Sunspots

PARTICULARS are given to date (July 8) of two recent sunspots noteworthy on account of size, which places them in the category of naked eye spots

Date on Disk	Central Meridian Passage U T	Latitude	Maximum Area
July 3 13	July 7 2	14° N	1000 units
4 17	10 7	13 S	850

The unit of area is one millionth of the sun s visible hemisphere A sunspot of area 500 millionths, not too near the edge of the disk, is usually visible to the naked eye when the brilliancy of the disk is sufficiently reduced by a dense glass filter

Addendum (July 12) Another large spot has come over the eastern limb in south latitude 11°, the time of central meridian passage being July 15 1 By July 11, the area of the spot had reached 1 500 units

Announcements

SIR WILLIAM BRAGG, president of the Royal Society and director of the Royal Institution, has been elected a foreign associate of the Paris Academy of Sciences The number of foreign associates of the Paris Academy is limited to twelve, and the only other living British man of science in this distinguished company is Sir Joseph Thomson

SIR ARTHUR OLVER, until recently animal husbandry expert, Imperial Council of Agricultural Research, India, has been appointed Principal of the Royal (Dick) Veterinary College, Edinburgh, in succession to the late Principal Bradley

THE following have been appointed to fill the vacancies which will occur in the Council of the Institution of Electrical Engineers on September 30 *President* Dr A P M Fleming, *Vice President* Prof C L Fortescue, *Hon Treasurer* Mr W McClelland, *Ordinary Members of Council* Dr P Dunsheath, Prof R O Kapp, Mr A P Young, Dr. L G Brazier

DR EDGAR COCHRANE, of Accra, Gold Coast, has been awarded the North Persian Forces Memorial Medal for 1937 for his paper on tuberculosis in the tropics published in the *Tropical Diseases Bulletin* last year

THE Howard Prize (an aneroid barometer, given annually for the best essay on a selected meteorological subject) of the Royal Meteorological Society has been awarded to Cadet Colin Derek Thorpe, of H M S *Conway* School Ship Consolation prizes have been awarded to Cadet Arthur Vernon Baker (H M S *Conway*) Cadet Godfrey Harry Hayes (H M S *Conway*) and Cadet Richard Christopher Stancliffe Hurst (H M S *Worcester*) who were bracketed second The subject of the essays was Clouds

THE following appointments and promotions in the Colonial Service have recently been made G F Boizot, assistant analyst, Malaya, Dr Campbell, plant pathologist, Zanzibar, G R Howat analytical chemist, Medical Department Gold Coast, W A Tooke chemist, Geological Survey Department Malaya, E J Gregory (manager of the St Augustine Experimental Station, Trinidad), agricultural officer Uganda, M D Lumsden (veterinary officer) assistant officer in charge, Government Stock Farm, Trinidad

LIEUT COLONEL E v WHITBY of the Royal Army Medical Corps, has been awarded the Leishman Memorial Prize for 1937 consisting of a silver medal and a sum of £30 The prize is awarded annually to an officer of the Royal Army Medical Corps or the Army Dental Corps for work of outstanding merit

PROF REYNALDO DOS SANTOS, of Lisbon, has been awarded the Violet Hart gold medal for his work on vascular surgery on the occasion of the recent Surgical Congress of the Southern United States

PROF WOLFGANG OSTWALD, professor of colloid chemistry at Leipzig, and Prof Eric Martini, professor of medical zoology at Hamburg, have been nominated as honorary members of the Rumanian Academy of Sciences at Bucharest

THE June issue of the *London Hospital Gazette* is a bicentenary appeal number containing an article on the staff in the past by Dr Robert Hutchison consulting physician to the hospital, the growth of the hospital laboratories by the director, Dr P N Panton, nursing at the London Hospital by the matron, and the coming bicentenary of the Hospital and College by Dr Cecil Wall, senior physician to the hospital

SIR HOWARD GRUBB, PARSONS AND Co have taken over the astronomical instrument and observatory equipment business hitherto carried out by Messrs Cooke, Troughton and Simms, Ltd, of York The address of Sir Howard Grubb, Parsons and Co is Astronomical Instrument Makers, Optical Works, Walker Gate, Newcastle on Tyne, 6

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK S LETTERS APPEAR ON P 118

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Formation of Milk

WE have administered labelled (radioactive) sodium phosphate to goats and investigated to what extent phosphorus present in different compounds extracted from the blood and the milk became labelled In two cases the goat was killed after the experiment and the phosphorus compounds present in the organs investigated as well Some of the results obtained are seen in the accompanying table

Activity per mgm P in milk (Activity of plasma inorg P after 4½ hours taken as 1)			Activity per mgm phosphatide P extracted from milk and organs after 4½ hours	
Interval after the start of the experiment	Fraction	Activity per mgm P	Fraction	Activity per mgm P
0 2 hr	Inorg P	0 68	Milk	0 09
	Casein P	0 54	Plasma	0 02
	Ester P	0 32	Corpuscles	0 01
2 4½ hr	Inorg P	1 79	Milk gland	0 13
	Casein P	1 71	Liver	0 09
	Ester P	1 16	Kidney	0 11
4½ 6½ hr	Inorg P	1 71	Activity per mgm P of milk ester P accumulated in 0 3 hours	
	Casein P	1 71		
	Ester P	1 34		
23 26 hr	Inorg P	0 40	Hydrol 7 min	0 76
	Casein P	0 55	Hydrol 60 min	0 68
	Ester P	0 49	Remaining fraction	0 34
			Milk inorg P	1 48

Inorganic phosphorus The inorganic phosphorus extracted from the milk produced in the first two hours after the subcutaneous injection of the labelled phosphorus, shows considerable radioactivity Should the milk contain only those inorganic phosphorus atoms which were located in the plasma at some time after the start of the experiment, the specific activity of the milk inorganic phosphorus should be as high as that of the plasma inorganic phosphorus In making such a comparison, it must be borne in mind that the specific activity of the plasma inorganic phosphorus rapidly decreases with increasing time through interaction of plasma phosphate phosphorus with that of bone and other tissue[1] No definite conclusion can therefore be drawn from comparing a single value of the specific activity of plasma and milk phosphorus By following up, however, the change of the specific activity of the plasma inorganic phosphorus and milk inorganic phosphorus with time, we find that it takes 3–4 hours for the milk inorganic phosphorus to be almost entirely composed of individual atoms which had been present in the plasma after the start of the experiment

In milk produced shortly after the start of the experiment, a large part of the phosphorus atoms present were those which were located in the milk gland when the labelled phosphorus was administered The replacement of the gland inorganic phosphorus by plasma inorganic phosphorus is thus comparatively slow because of a slow rate of penetration of the phosphate ions through the cell walls Heavy water, on the other hand, injected simultaneously with the labelled phosphate was already, after a short time, equally distributed between plasma and milk, because of the low resistance water molecules encounter when penetrating through cell walls

Casein phosphorus The comparatively high specific activity of the casein phosphorus is only compatible with the assumption that the phosphorus atoms utilized in the synthesis of the casein in the milk gland are drawn from the inorganic phosphorus of the plasma From the difference in the rates at which the active casein phosphorus and the active inorganic phosphorus present in the milk are formed, the time of formation of the casein in the gland cells can be estimated to be about 1 hour

Ester phosphorus The rate of formation in the milk gland of the average labelled phosphorus ester molecule is lower than that of the average casein molecule (cf table) 1½ hours after the administration of radioactive hexose monophosphate (kindly presented to us by Prof Parnas) injected into the veins of the goat, an appreciable amount of labelled ester was found in the milk, while another larger part of the activity was found in the inorganic milk phosphate This result shows that a rapid enzymatic breakdown of the hexose monophosphate and rebuilding of ester molecules takes place in the gland The milk gland contains thus enzymes having the same action on *hexosemonophosphate* as Robison and Kray s[2] bone extracts, however, the bulk of the esters present in the milk are acted on by enzymes present in the gland at a much slower rate Similar behaviour is shown by the mixture of phosphorous esters present in the blood[3]

Phosphatide phosphorus The formation of active phosphatide molecules is, as seen from the table, a slow process The individual phosphatide molecules present in the milk were mainly built up in the milk gland and not taken up as such from the plasma (as is the case with the yolk phosphatide[1]) This follows from the fact that the specific activity of the phosphatide phosphorus extracted from the milk gland and also from the milk itself is higher than that secured from the phosphatide of the plasma The view is often encountered that the milk fat originates from the plasma phosphatides which decompose in the milk gland, supplying fat and inorganic phosphorus This view is entirely incompatible with the results obtained by us To mention only one argument, we find the phosphatide phosphorus of the milk to be slightly, the inorganic phosphorus present to be strongly, active The latter can therefore only originate from the highly active inorganic phosphorus of the plasma

It is well known that different milk fractions, secured consecutively within a short time, have a markedly different fat content As we find[3] that the inorganic phosphorus extracted from these fractions has a different specific activity, we have to conclude that these fractions cannot originate from an initially homogeneous liquid So we arrive at the result that some of the milk gland cells give off milk much more readily than others, but that some even of the first-mentioned cells retain a large part of their solid milk constituents, particularly the phosphatides (and fats) Not only are phosphorus compounds present in the milk not formed during the act of milking, as often assumed, but such compounds contained in the last fraction secured during the act of milking are partly of earlier date than those present in the immediately preceding milk samples

We wish to thank Profs Bohr Brønsted and Lundsgaard for numerous facilities kindly placed at our disposal, Prof Lawrence for the generous gift of some powerfully active phosphorus preparations and Miss Hilde Levi for carrying out the counting experiments

Concentration and Measurement of Atmospheric Ozone

MORE than ninety years ago C F Schönbein, the discoverer of ozone claimed its presence in atmospheric air[1], his ozonometer, consisting of paper soaked in potassium iodide and starch indicated interesting variations in the ozone content of air which were deemed of such importance by meteorologists and medical men that regular observations were started in most civilized countries We possess daily records of many decades, and the statement that millions of ozone determinations have been carried out[2] is probably not exaggerated

Unfortunately, these numerous measurements are open to the criticism that the chemical reaction used is not specific, other oxidizing agents having the same effect on potassium iodide , as the presence in air of at least one of them, nitrogen peroxide, is certain, and can amount to the same order of magnitude[3] the value of all those 'quantitative' ozone records is extremely doubtful Since attempts to identify it by specific reagents were unsuccessful, some chemists were even inclined to deny altogether the presence of ozone in the air

The direct spectroscopic determination of atmospheric ozone, though possible, is too difficult and costly for routine measurements We have therefore attempted to make the old chemical method reliable[4], and believe we have achieved this aim by introducing the following refinement the current of air (at least 500 litres) is not passed directly over (or through) the reagent, but its ozone content is first concentrated by condensation, and then separated from less volatile oxidizing agents, for example, nitrogen peroxide, by fractional distillation This procedure became possible after we had found that even in very low concentration (about one part in 100 million parts of air) ozone can be condensed on silica gel at liquid air temperature, and re distilled without loss If, in the latter process, the temperature is not allowed to rise above −120°, the whole of the nitrogen peroxide is held back, and is itself available for colorimetric tests (We employed for this purpose the 2 4 xylen 1 ol method[5]) The determination of the purified ozone can be carried out in the usual way[6] in a few minutes by titration with potassium iodide and starch

It is also possible to collect the re distilled ozone in a glass tube with quartz windows and to measure its absorption of ultra violet light Thus an ozone thickness equal to the ozone in more than 30 kilometres of air can be concentrated in a short tube no complications arise through the absorption of light by dust particles and Rayleigh scattering and the calibration can be effected by direct chemical analysis consequently the spectroscopy of the atmospheric ozone becomes much simpler, and we hope, in collaboration with Prof H Dingle, to work it out in a quantitative way

The photographic records of the characteristic ozone absorption so far obtained show conclusively that the volatile part of the condensate is actually ozone Another qualitative proof was provided by the use of tetramethyl base , a colorimetric reagent less sensitive than the iodine starch method but strictly specific[7] thanks to the preceding concentration, the ozone was sufficient for the application of this method and these tests too, were convincing

The accompanying table gives some of the results obtained As can be seen, we also determined in each case the nitrogen peroxide content In most experiments the analysed air was taken in South Kensington outside the laboratory, in a wide street with little traffic (Imperial Institute Road) As it was conceivable that both the ozone and nitrogen peroxide values in a town atmosphere are very different from the average, we thought it advisable to carry out a few parallel experiments at Kew Observatory, which is near the open country

Date (1938)	Weather	(Per cent by volume) × 10^4	
		Ozone	Nitrogen peroxide
Feb 7	Dull and cold	0 8	0 4
8	Dull and overcast	0 5	0 6
10	Raining	0 8	0 1
14	Heavy snowstorm	0 8	<0 05
22	Dull and overcast	1 1	1 2
Mar 3	Warm and sunny	0 9	1 3
7	Spell of very fine weather warm and sunny	1 9	<0 05
10		0 6	<0 05
14		0 9	<0 05
17	Dull and overcast	1 1	0 5
May 6	Cloudy morning sunny afternoon S Ken	2 3	0 2
	Kew	2 3	< 0·05
10	Bright morning cloudy afternoon S Ken	1 3	0 5
	Kew	2 2	0 3

The mean value of the London ozone measurements is 1 1 × 10^{-4} vol per cent We hope later to apply this method to a systematic determination of the dependence of the ozone content on meteorological factors, geographic position and altitude , perhaps it will be possible also to measure the ozone in the higher atmosphere by the use of aeroplanes

In conclusion, we wish to thank Prof H Dingle heartily for his collaboration on the spectroscopic side, and Dr F J W Whipple for granting us facilities to work at Kew Observatory

Luminescence of Solids at Low Temperatures

THE fluorescence of solids has generally been regarded as a comparative rarity confined to a few groups of compounds, of which the sulphides of zinc and calcium, the uranyl salts, and a number of platino cyanides are amongst the better known Recent observations at low temperatures suggest that many other compounds are fluorescent, and a fairly wide distribution throughout the periodic table is indicated Table 1 gives a list of some of the more striking compounds, a number of which are not fluorescent at room temperature The fluorescence intensity of a few of these compounds is weak even at the temperature of liquid nitrogen, compounds also showing appreciable fluorescence at room temperatures are indicated in italics

TABLE 1 COMPOUNDS FLUORESCENT AT LOW TEMPERATURES

Anhydrous beryllium sulphate	Samarium sulphate
Anhydrous magnesium chloride	Silicic acid
Zinc oxide and chloride	Stannous chloride
Zinc sulphate anhydrous	Lead nitrate
Zinc orthosilicate	Lead chloride
Zinc sulphide	*Phosphorus*
Cadmium chloride	Antimony trichloride
Cadmium bromide	Bismuth trichloride
Cadmium iodide	Anhydrous manganous chloride
Mercuric chloride	Anhydrous manganous bromide
Mercurous chloride	Manganous bromide
Cuprous chloride	*$PtCl_2$ dipyridyl red form*
Silver chloride and bromide	$PtCl_2$ dipyridyl yellow form
Indium acetyl acetone	Sodium fluorescein
Samarium sesquioxide	Rhodamine G B 500

Detailed comment is not possible here, but it may be remarked that the zinc sulphide mentioned in the table was sufficiently pure to be non fluorescent at room temperature under a strong focused beam of ultra violet light Cuprous chloride is of interest as it gives two different spectra according to the temperature, the effect is conveniently observed as follows A thin copper strip is coated at one end with a layer of chloride and cooled to approximately 80° K On quickly removing the strip from the cooling liquid and placing in the ultra violet beam, a narrow band of red fluorescence moves rapidly along the specimen from the warmer end As the red fluorescence disappears, it is followed by a much wider band of green fluorescence, the temperature range of this being very roughly −150° C to −100° C

It is considered that the fluorescence of some of these compounds is a feature of the pure substance, but it is naturally difficult to be sure of this when very minute traces of impurity may be effective, this aspect of the problem is under investigation Some of the compounds were extremely pure, and the remainder were of reasonable (analytical reagent) purity If the fluorescence observed should prove to be that of impurity phosphors, it is clear that the examination at low temperature provides a more sensitive test of purity than the more normal procedure

Lowering of temperature gives rise in many instances to a marked narrowing of the diffuse emission bands of fluorescent solids While this narrowing frequently leaves much to be desired, it is sometimes sufficient to indicate features that would not otherwise be observable In the present instance it has been used to compare the spectra of a number of impurity phosphors all activated by manganese, at temperatures between 20 K and 85° K Table 2 summarizes the results

TABLE 2

LOW TEMPERATURE SPECTRA OF IMPURITY PHOSPHORS ACTIVATED BY MANGANESE

Substance	Temp	Main features of fluorescence emission spectrum	
Zinc orthosilicate	20° K	4000 A 000 A	Mod strong continuum
		03 A	Sharp edge
		[illegible]	Weak line
		100	Weak line
		1	Strong line
		180	Mod strong line
		220	Centre of intense band
		320	Mod strong line
		5900 6300	*Weak band*
Zinc sulphide	20 K	*5940*	*Intense narrow band*
Zinc beryllium silicate	85 K	4000 A 000 A	Weak continuum
		300 A	Mod strong broad band
		920 A	*Strong narrow band*
Cadmium chlorophosphate	85 K	4000 000	Mod continuum
		5950 A	*Intense narrow band*
Cadmium silicate	8 K	4000 A 000 A	Mod strong continuum
		5960 A	*Mod strong narrow band*
Cadmium iodide	85 K	*5900* A	Broad continuum with peak at approx this wave length
	(300° K)	*6325* A	*Narrow band*
Silver chloride	85° K	[illegible]	Strong band
		6210	*Mod strong narrow band*

In this series zinc orthosilicate is the only substance showing a number of sharp lines in addition to a diffuse background Comparison of the spectra indicates that all six substances have a band lying between 5900 A and 6000 A Allowing for the varying nature of the matrix lattice, it is considered that this band is to be associated with the manganese impurity common to all If this suggestion is maintained, it follows that the fluorescence of these compounds is at least in part due to transitions within the manganese atom or ion Some support is given to this idea by the observed fluorescence of pure manganous compounds (Table 1), the two compounds noted each giving a narrow band at 6325 A approximately In the case of zinc orthosilicate, where the 'manganese band' is weak, the observed resolved spectrum in the green may also be due to manganese excited differently because of some difference in the number or distance of nearest neighbouring atoms. It also seems possible, however, that the manganese impurity may have here a different major role that of stimulating fluorescence in the matrix lattice If this explanation is the true one, the zinc atoms contributing to the fluorescence would be those nearest to the impurity manganese atoms The fluorescence of calcium oxide recently reported by Ewles[1] would appear to be of this type

Rod-shaped Clay Particles

THE minerals found in clays and soil colloids are usually considered to be plate shaped and to have layer lattices built up from sheets of silicon - oxygen tetrahedra This may be true in the majority of cases, but rod or needle shaped particles can also occur and should not be overlooked Their presence may be due to one of the following two reasons

(1) Layer lattice minerals can under special conditions of growth be developed as rods

(2) Rod or needle shaped minerals may exist, with a structure based on single or double chains of silicon - oxygen tetrahedra similar to pyroxenes and amphiboles

An example of (1) was found in the crystals of pyrophyllite from Tres Cerritos, Sierra Nevada, California, which I received through the courtesy of Prof C E Tilley of the Department of Mineralogy, Cambridge Pyrophyllite usually occurs in flakes and its structure has been determined by J W Gruner[1] from powder photographs as a monoclinic layer lattice with Si Al Si layers parallel to (001) The crystals from Tres Cerritos form long, thin rods radiating outwards from the centres of spheres Sufficiently thin crystals give good X ray single crystal reflections with a period of 5 1 A for the needle axis This corresponds to the [100] direction of Gruner s structure, and also to the chain length unit (*c* axis) in amphiboles and pyroxenes According to their structure and orientation, the pyrophyllite rods have only one perfect cleavage parallel to their elongation The fact that bentonite suspensions may show negative streaming double refraction was taken by A v Buzágh[2] as evidence of the presence of rod shaped particles It is now well known that the main constituent of bentonite is the layer lattice mineral montmorillonite

An example of (2) seems to be the series of clay minerals known as palygorskites, which includes the minerals sepiolite and attapulgite Sepiolite is the magnesian end member, and a sample from Ampandandrava, Madagascar with a period of 5 3 A in the fibre direction, has been extensively studied by H Longchambon[3], who came to the conclusion that the whole group had an amphibole like structure, based on double chains of silicon oxygen tetrahedra The experimental evidence is, however, not quite conclusive, and J de Lapparent, who first described the mineral attapulgite[4] as the main constituent of two fuller's earths, maintains a mica like structure for the group of palygorskites The water relationships for sepiolite and attapulgite are similar to those for montmorillonite, but no lattice shrinkage or expansion has been observed, it is, therefore, possible that in these minerals channels of water between rings of Si_4O_{11} chains play the part of the sheets of water in montmorillonite

A New Phosphoric Ester Isolated from the Products of Yeast Juice Fermentation

THE fermentation hexosemonophosphate (Robison ester[1]) isolated from the products of fermentation of glucose, mannose, or fructose by yeast juice, consists mainly of an enzymic equilibrium mixture of glucose, fructose and mannose 6 phosphates[2,3], but as usually purified by means of the lead and barium salts may also contain traces of trehalosemonophosphate, phosphopyruvic acid, triosephosphate, α glycerophosphate etc A typical specimen of the Robison ester also gives a green colour when heated with orcinol and hydrochloric acid, the amyl alcohol extract showing an absorption band about 670 mμ This fact indicates the presence of an unknown ester in the mixture, since the reaction is not given by any of the above mentioned phosphoric esters, and differs from that given by pentoses (in absence of iron) in the position of the absorption band, it was found, however, that an identical reaction is given by the 7 carbon atom sugar mannoketoheptose isolated from the Avocado pear by La Forge[4]

The isolation of the ester responsible for the colour reaction has been achieved by a preliminary oxidation of the mixed ester with bromine at neutral *p*H, the whole of the aldose esters being removed as insoluble phosphohexonates, followed by fractional crystallization of the brucine salts of the residual sugar phosphates The barium salt, prepared from apparently homogeneous brucine salts giving an intense blue colour with orcinol - hydrochloric acid, has $[\alpha]_{5461} + 8°$, the analysis agrees with that of a ketoheptose phosphate On hydrolysis with bone phosphatase at neutral *p*H the ester gives rise to a non fermentable reducing sugar, giving the colour reactions of a ketoheptose, the properties of the sugar, which has not yet been obtained in a crystalline state, are not identical with those of mannoketoheptose but indicate that it may be a mixture of this sugar with others of a similar type

In normal hydrochloric acid at 100°, the ester is hydrolysed smoothly with a velocity constant, $k = 4 \times 10^{-3}$, practically identical with that of fructose 6 phosphate, on heating with phenyl hydrazine and glacial acetic acid, a precipitate containing 4 per cent phosphorus was formed, but the product could not be obtained crystalline These facts suggest that the ester is not a 1 phospho derivative since the known 1 phospho sugars are rapidly hydrolysed in acid solution and form phosphorus free osazones The ester is formed during the fermentation, constituting 1 2 per cent of a typical Robison ester, but is not present in the similar monophosphate fraction (Embden ester) prepared from muscle extract.

The mechanism of its formation affords an interesting problem in the enzymic synthesis of carbohydrate during the fermentation of hexoses. Meyerhof, Lohmann and Schuster have demonstrated the enzymic formation of ketosephosphates by the condensation of dihydroxyacetonephosphate with aldehydes in presence of aldolase[5] and this reaction might account for the formation of a 1 phosphoketoheptose. The enzymic transference of the phosphoric acid group to another position might then take place as in the case of the Cori ester glucose 1 phosphate[6].

Oxygen Transport with Fully Reduced Arterial Hæmoglobin in the Human Being

It has been long known that infants, born with a transposition of the pulmonary artery and the aorta may be living with a very cyanotic appearance. In two cases which lately came under our observation not a trace of oxygenated hæmoglobin was found in the arterial blood with methods certainly sensitive to one per cent of oxygen saturation, although no further marked symptoms of oxygen want were present. The oxygen consumption of the two patients was not far from normal and, though we are not able to give a complete explanation of the curious conditions, we have found some interesting properties in the blood of one patient we had an opportunity of studying somewhat closely at the age of four months.

The hæmoglobin as judged by its spreading properties at various hydrogen ion concentrations its oxygen dissociation curve its alkaline resistance its vital decomposition and formation (icterus neonatorum) was normal, the concentration varied between 17 and 20 per cent. There was slight acidosis, the *p*H of the blood was in the normal range.

Whereas the oxygen capacity was calculated from the hæmoglobin percentage to be 27 vol. per cent the Barcroft manometric technique gave an absorption of 38 vol. per cent of oxygen by the arterial blood. Saturation of this blood by carbon monoxide decreased the uptake of oxygen by the expected 27 vol. per cent, leaving an extra absorption of 9 vol. per cent. The same treatment of samples of normal blood always reduced the oxygen absorption to zero.

So the patient's blood appeared to have, besides its normal oxygen capacity, depending on the presence of reduced hæmoglobin, an extra capacity of 9 vol. per cent, the rate of absorption by this extra capacity was about one fourth of that by the normal capacity at room temperature. The extra capacity was not found in the plasma, but only if corpuscles were present, it was not much influenced by small amounts of cyanide or iodoacetate.

The relation between the normal hæmoglobin and the extra capacity is indicated by the following observation. The superficial venous blood of the patient is found to be 20 25 per cent oxygenated by cutaneous oxygen absorption, if this blood is kept in a closed syringe for 30 min. at 37°, its hæmoglobin is at least 95 per cent reduced. Also, if one mixes equal parts of the patient's fully reduced arterial blood and of normal fully oxygenated blood (having the same hæmoglobin content) the resulting mixture after 2 min. is not 50 per cent but only 35 vol. per cent saturated. Again if the patient's blood is 30 per cent oxygenated and then kept for 30 min. at 37°, it is nearly reduced and now its oxygen capacity corresponds to the hæmoglobin content, the extra capacity being saturated now.

We have not been able to detect the biochemical mechanism of this extra capacity, but wish to direct attention to this probably not very rare occurrence of oxygen transport with the arterial blood in the completely reduced state.

Sugar Content of the Hormones of the Pituitary Anterior Lobe and of the Gonadotropic Hormone from Pregnancy Urine

During our investigation of the active principles of the pituitary anterior lobe and of the gonadotropic hormone from pregnancy urine we established the fact that the gonad stimulating factors of the anterior lobe and, more particularly prolan from pregnancy urine contain considerable quantities of carbohydrate, even when in a highly purified state. This carbohydrate could not be removed nor its percentage decreased by treatment with weak alkalis or by prolonged and repeated dialysis. Such properties seem to indicate the presence of glycoproteins in the gonadotropic protein factors. The sugar may be combined with the protein in the form of a polysaccharide. The nature and quantity of the basic carbohydrate was determined by means of the orcine sulphuric acid reaction. The gonadotropic factors of the pituitary anterior lobe contain 6 per cent (maximum value) of mannose, prolan obtained from pregnancy urine contains 19 per cent (maximum value) of mannose or possibly of galactose, or of both these hexoses (the preparations have not yet been tested for hexosamine).

The existence of mannose (or galactose) in the gonadotropic substances is not surprising. Sørensen and Haugaard discovered that the sugar protein complexes generally contained mannose or galactose (or both) and not glucose as previously thought. On the other hand, the large percentage of carbohydrate, in comparison with the other sacchariferous proteins, is very noteworthy. It is possible that the physiological activity of the gonadotropic factors is due to, or connected with, the presence of such glycoproteins. The rather remarkable observation was made that, on isolating the gonadotropically active portions of the pituitary anterior lobe, and of pregnancy urine, the sugar content increased. The difficultly soluble portion of the anterior pituitary extract shows no, or only a weak, sugar reaction, the prolactin fraction being practically free from sugar.

It should be mentioned that extracts of the pituitary gland and of pregnancy urine contain, in addition to the sugar present in combination with protein, comparatively large quantities of sugar in the uncombined state and thus separable by dialysis This sugar is very probably utilized in the synthesis of the hormone

Limited and Unlimited Swelling of High Molecular Substances

THE material available at present allows the establishment of a hypothesis for the mechanism of the transition limited → unlimited swelling (that is, dissolution) of high molecular compounds On one hand Brønsted[1] and Schulz[2] have discussed the distribution of molecules of great size over several phases, on the other hand Hofmann, Frenzel and Csalan[3] and Katz[4] have investigated the one dimensional swelling of 'graphitic acid

The swelling of high molecular substances consisting of chain molecules however, is more complicated, since they may swell in two dimensions For the purpose of establishing a simple model the following assumptions may be made (1) The solid body consists of a number of long chain molecules of identical structure and length (2) The lattice energy has a constant value for all molecules (3) The sorbing activity of a group is independent of its place within the chain, the number of swelling agent molecules participating in the formation of the coating is proportional to the chain length (4) Chain molecules of different degree of solvation are miscible The probability, however, that the swelling agent molecules are distributed unequally over the chains dwindles in the case of long chains, and becomes zero for 'chains of infinite length as shown by the following consideration

The total amount of swelling agent taken up, Σ_n, is given by an isotherm

$$\Sigma_n = f(p), \qquad (1)$$

where p is the swelling agent pressure The transformation gel (solvation degree Σ_n) → gel (solvation degree $\Sigma_{n+\Delta n}$) takes place if

$$\Delta F_{\Sigma n} = \Delta H_{\Sigma n} - T\,\Delta S_{\Sigma n} < 0, \qquad (2)$$

where ΔF, ΔH and ΔS are the molar changes of free energy energy and entropy, Δf, Δh and Δs are the corresponding quantities for one mole of the monomer, π is the polymerization degree In consequence of assumption (3), the heat of swelling, to a first approximation, is given by

$$\Delta H = \pi\,\Delta h \qquad (3)$$

ΔS is different from zero as found by Fricke and Luke[5], and Stamm and Loughborough[6], Katz[7] suggested that the entropy change is mainly due to an orientation of the sorbed molecules Therefore, it may be written

$$\Delta S = \pi\,\Delta s \qquad (4)$$

Accordingly, the ratio $C^n/C_{n+\Delta n}$ of Σ_n molecules and $\Sigma_{n+\Delta n}$ molecules within the gel is given by

$$\frac{C_n}{C_{n+\Delta n}} \qquad e^{\frac{\pi}{R}\left(\frac{\Delta h}{T} - \Delta s\right)} \qquad (5)$$

When the numerical value of π is considerable, uniform swelling takes place The swelling is limited, until an amount of swelling agent Σ_{crit} is taken up sufficient to saturate completely the forces acting between neighbouring chains If

$$\Delta f_{\Sigma\text{crit}} < 0, \qquad (6)$$

dissolution (unlimited swelling) is effected This condition is fulfilled, if

$$\Delta h_{\Sigma\text{crit}} - T\,\Delta s'_{\Sigma\text{crit}} < RT \ln \frac{p}{kRT} \qquad (7)$$

where $\Delta s'$ is the solvation entropy change, p the pressure and k a constant The upper limit of p is given by the saturation pressure of the swelling agent Starting from equation (7), it will be possible to estimate the numerical value of $\Delta f_{\Sigma\text{crit}}$ in different systems

A substance, capable only of limited swelling at ordinary conditions, may dissolve, when the saturation pressure of the swelling agent is increased for example agar The interaction of the polar agar molecules is comparatively strong In other cases the interaction may be still stronger so that complete separation cannot be effected, for example in the cases of vulcanized rubber, and of Staudinger's[8] insoluble polystyrene

Intermicellar swelling is possible on the basis of a secondary structure This process is more complicated but essentially not different from that of intramicellar swelling

The above assumptions and the numerical values will be discussed in detail elsewhere

A Simple X-Ray Dosimeter

ALTHOUGH the direct current generated by a photo electric cell exposed to short wave radiation, extending from the region of the *Grenz Strahlen* to the gamma rays, is only of the order of one hundredth of that induced by visible light[1], it can be used as an accurate measurement of the radiation value In this Institute, it has for some time been used as a routine method of calibration of the dosage (in r units) applied to *Drosophila* cultures

The apparatus is extremely simple, consisting of a Weston photo electric cell, shielded from visible light by a wrapping of black (photographic) paper, connected by ordinary flexible leads (which need not be shielded and can be of any reasonable length) to a d'Arsonval mirror galvanometer, reading to 10^{-8} amp, and the usual illuminating system The galvanometer gives a deflection of 300 mm at one metre for a current of 1 microamp, this is very nearly the current produced by the Weston cell when exposed to an intensity of 300 r per minute The readings are linear between limits of 20 r and 300 r, with voltages of 40–120 kv applied to the tube The cell is usually placed at distances of 12–25 cm from the target, and at the same level as the irradiated material If a distance of more than 25 cm is employed, it is advisable to connect *two or four* cells in parallel the effect is approximately proportional to the number, but it may be necessary to select cells which match each other's characteristics In general, the cells are very equal in their output, and a comparison of cells five years old with cells one year old showed no significant difference

In cases where high intensities and short distances are used, the galvanometer may be replaced by a direct reading microammeter For example, using four cells in parallel at 12 cm from the target with an output estimated at 1 000 r, the reading was 12 microamperes with a single cell it was slightly more than 3

Such an arrangement has several advantages it is compact and portable, it is not affected by atmospheric conditions, gives a continuous reading which *immediately responds to fluctuations* of the radiation produced by voltage changes or thermal variations in the tube The cell can usually be placed in contact with the object radiated and once calibrated, by means of a dosimeter or a biological test can be relied on to give reproducible results It can be recommended to all who require a rapid and simple method of X ray dosage

Cytology of Metamorphosis in the Culicinæ

C R RIBBANDS¹, commenting on my recent communication², states that I apparently overlooked the work of Holt³ on the gut of *Culex* References to Holt's work may be found in two of my papers⁴, which appeared in well known journals during the past two years Having been a student of Prof Metz, I am also familiar with his work on the paired association of somatic chromosomes Indeed the present investigation was undertaken at the suggestion of Prof Metz and much of the work was done under his supervision

Regarding the several points of disagreement between Holt's results and mine it may be noted that the evidence for my results has been given briefly in four preliminary reports, referred to in this⁴ and a former communication², and that a detailed account with photomicrographs is in the current issue of the Contributions to Embryology of the Carnegie Institution of Washington

A possible explanation of our different results may be found in the technical advances of the past twenty years Holt's work was based entirely on sectioned material The iliac epithelium of *Culex* has the form of a narrow tube, the wall of which is a single layer of cells These cells are usually in the shape of a flattened ellipsoid The tube itself is not straight and different regions may be in different states of contraction and expansion Judging cell size from sections of an organ of this type is very difficult, if at all possible Camera drawings of such sections yield no certainty regarding cell size Yet a few such camera drawings by Miss Holt are taken by Ribbands as showing conclusively the lack of correlation between cell size and chromosome number

In addition to sections and aceto carmine smears, my best evidence for a correlation between cell size and chromosome number came from whole mounts of the larval hind gut, dissected out and stained by the Feulgen technique Whole mounts prepared in this way are invaluable in the study of metamorphosis All the cells are present whole, essentially undistorted and in their normal position The preparation is transparent and the upper and lower walls can be examined under the oil immersion In a series of such preparations relative cell size is apparent and the fate of each tissue during metamorphosis can be clearly followed

⁴ Berger C A *Proc Nat Acad Sci* 22 186 (1936) *Amer Nat* 71 187 (1937)

I REGRET that I wrongly concluded¹ that Prof C A Berger had overlooked the work of Holt², but no reference to it appears either in his original letter³ or in either of the other two preliminary accounts referred to therein in which he outlined his results, some identical with those of Holt others in contradiction to them His communications contained no mention of his own technique which therefore could not be compared with that of Holt

If chromosome number is correlated with cell size in this instance another example is added to a long list of similar cases⁴, but examples of lack of correlation are still known⁴ Berger's data relative to cell size have not been published, but he states that in the ileum of *Culex pipiens* the smallest cells, without complexes have a nuclear diameter of 3μ, and that greatest diameters of nuclei range from 10μ to 17μ' ⁵, these latter cells having complexes of up to 192 chromosomes³ Holt illustrated a prophase nucleus (Plate 2, Fig 19) *containing only* 18 *chromosomes*, which had a greatest diameter of about 13μ Since Holt's drawings are from sections it is unlikely that the nucleus has been artificially flattened, as it could be when using either smears or the new method which Berger describes above, and therefore this one example indicates that there is no exact correlation between chromosome number and nuclear volume in this tissue Cell volume is even less likely to be proportional to chromosome number, since instances are known in which chromosome volume affects nuclear volume without altering cell volume ⁶

None of the six preliminary reports of Berger give any proof of his more important disagreement with Holt's results, concerning the possibility of a regular reduction in the chromosome numbers in these cells so I await his detailed account in the hope of a *solution both of this problem and of the one concerning* correlation between cell size and chromosome number

A Triploid Asynaptic *Allium amplectens* from California

TRIPLOID forms of the Californian species *Allium amplectens* Torr ($2n=21$) are characterized by almost absolute lack of chiasmata at meiosis In some slides no chiasmata at all occur, in other slides there may be found 1 chiasma in about 500 pollen mother cells

The pachytene chromosomes are paired in the manner normal for triploid species and no structural differences between homologous chromosomes are observed Homologous chromosomes are held together during diplotene exclusively by the relational coiling

The 21 univalents present at the first metaphase are arranged in an equatorial plate Their centromeres remain undivided and all the chromosomes are included in one interkinese nucleus

The second division takes place regularly and leads to the formation of pollen dyads Almost all the pollen grains investigated exhibit 21 chromosomes, showing the regularity in function of this meiotic abnormality

Tetraploid forms, collected at the same locality as the triploids, have normal chiasma conditions, and their meiosis runs a regular course The pollen grains are formed in tetrads and contain ± 14 chromosomes

The asynapsis of *Allium amplectens* is evidently genetically caused, and is not due to failure of pairing It is of a more extreme type than the asynapsis earlier reported from *Zea*[1] and *Crepis*[2]

Effects of Injury on the Teeth of *Selachii*

IN 1784 Andre[1] attempted to prove "succession' of teeth in cartilaginous fishes, illustrating his paper by a picture of a vertical row of divided teeth at the site of a spine embedded in the jaw of *Galeocerdo* He contended that the abnormal teeth had developed subsequent to the injury

Last year, Dr E W Gudger[2] reported similar splitting of teeth and one in which five corresponding teeth had been severed where they overlap those of adjacent rows in *Caracharhinus limbatus* He also attributed the abnormality to disturbances in the tooth germ

When considered together, the two halves of the split teeth correspond in every particular to normal teeth, except that the edges may have been smoothed off subsequent to the injuries received

Whilst extracting individual teeth from the jaws of *Caracharhinus*, I have sometimes caused identical splitting of teeth usually in the centre but sometimes at the side, but always in the same vertical row of teeth.

Careful consideration of the available literature fails to reveal evidence of teeth in the jaw of sharks having been formed subsequent to an injury or constant forward movement of a revolving gum

Points from Foregoing Letters

Prof G Hevesy and A H W Aten have administered radioactive sodium phosphate to goats and determined the amount of labelled phosphorus found in blood and in milk, after varying periods It takes 3-4 hours for the milk inorganic phosphorus to be almost entirely composed of individual atoms present in the blood plasma after the start of the experiment Casein is apparently formed in the gland cells in about an hour, while it takes rather longer for the formation of the esterified phosphorus and longest to form the phosphatide molecules

Prof F A Paneth and J L Edgar describe a method for the concentration of atmospheric ozone by condensation and fractional distillation The ozone was thereby separated from nitrogen peroxide and could be identified spectroscopically and determined chemically The ozone content of London air was found to vary considerably, its mean value was 1 1 × 10^{-6} vol per cent

A table of thirty compounds which fluoresce at low temperatures (80° K) and some of them at room temperature is given by Dr J T Randall The fluorescence in most cases is apparently that of the 'pure' compound A number of substances (ZnS, AgCl, etc) activated by manganese showed a common band between 5900 A and 6000 A

Dr G Nagelschmidt finds that crystals of pyrophyllite from California form long thin rods radiating outwards from the centres of spheres, and directs attention to the possible presence of rod shaped particles in other clays

Sugars containing 7 atoms of carbon in the molecule (similar to the mannoketoheptose isolated from the Avocado pear) have been detected by Prof R Robison, M G Macfarlane and A Tazelaar in Robison's ester (phosphate ester from the products of fermentation of glucose)

The arterial blood of a child four months old with transposition of the large vessels was found by Dr R Brinkman and J H P Jonxis to be completely reduced Its capacity for oxygen absorption was 1 3 times as large as the value calculated from the hæmoglobin content This was due to an extra capacity, interacting with the hæmoglobin system

Dr Max Hartmann and Fritz Benz find that the gonadotropic hormone of the pituitary anterior lobe and the gonadotropic hormone from urine contain a considerable quantity of sugar, the former 6 per cent of mannose and the latter 19 per cent Prolactin and thyrotropic hormone contain only a small amount of mannose It is possible that the sugar content is an essential factor for the activity of this hormone

The transition limited → unlimited swelling of long chain molecules is discussed by Dr E Broda He points out that the entropy change connected with swelling may be proportional to the chain length The transition occurs discontinuously at a certain activity of the swelling agent The transition point may be calculated from thermodynamical data concerning the solvation properties of the different groups.

Research Items

Social Symbiosis in Nigeria

AN attempt to adapt the well-established biological concept of symbiosis in social anthropology is made by Mr. S. F. Nadel (*Man*, June 1938) to define a new, that is, not yet formulated, and specific category of social organization. It applies to development, not in any abstract theoretical sense but as relating to concrete observable social processes, namely, the reorientation of a social system under certain conditions of external change and pressure. The facts examined concern the Nupe town of Kutigi in Northern Nigeria in which in a population of approximately 3,000 the development studied reaches back to events of some two hundred years ago. The population embraces four different tribal sections, originally distinct separate cultural groups which have migrated into their present domicile in different periods. The way in which these groups reacted and adjusted themselves to each other and eventually evolved a *modus vivendi*, represents the phenomenon it is proposed to call social symbiosis. Of the four groups two are of Nupe origin, one came from Bornu as wealthy traders and attained political and economic ascendancy, and the fourth consists of freed slaves, Yorubas imported to instruct the Nupe in weaving and dyeing. In the arrangement of the town, which is typically Nupe locality and tribal section, living place and migrational stratum, coincide. But between the separate localities and migration strata there exists to-day the closest co-operation which is the fruit of a far-reaching adjustment. The bonds of contact and common interest gain the significance of a specific and new social factor in the sphere of religion and kinship organization. The three activities of the sections—economic, religious, and social—can be shown to represent a reciprocity and interdependence linking section with section in the framework of a larger embracing social group unit, that is, a symbiosis, which represents the possible origin of clanship, and is one of the three possible developments in attaining a social equilibrium between diverse cultural groups—co-operation, symbiosis, and complete fusion.

Man of the Old Stone Age in America

PROF. E. B. RENAUD, of Denver University, whose explorations in search of archæological sites in Colorado and the neighbouring States have contributed largely to knowledge of the stone age cultures of the south-western United States, devotes his tenth report of "The Archæological Survey of the High Western Plains", sponsored by his University, to a study of the "Black's Fork Culture" of southwest Wyoming. This culture, which consists of series of stone implements of palæolithic type, or rather types, was first recorded so long ago as 1931. The difference in form, patination and appearance of age of these implements from the more usual type of stone implement of the area naturally attracted considerable attention, and its comparison with European palæolithic implements of a similar character provoked no little criticism. Further explorations in 1935 and 1936 increased the number of sites on which these implements occur to sixty-nine, situated in an area extending from Utah on the west to long. 109° on the east and lat. 43° on the north to the Utah line on the south. This area is drained by the Green River and its tributaries, of which Black's Fork is the most important and apparently the focal centre of the culture. Hence the name. In all, some four thousand specimens have been collected, besides collections in other hands. The camp sites, on which the implements are found, bear a general resemblance to one another. As a rule two cultures are present, an older and a recent, but the two are quite distinct, the older being associated with an older floor of occupation. The materials used are chert, moss agate and quartzite, the specimens falling into six classes, of which three belong to the chert group. Classified on broad lines the implements are bifaces and unifaces—coup de poing, choppers, end scrapers, side scrapers, pointes and blades. They belong to the early and middle palæolithic—pre-Chellean, Chellean, Acheulean, and Mousterian as well as Clactonian flakes. There is also a pebble industry, which is comparable with the rough quartzite pebble industry of the Upper Garonne. This terminology is used by Prof. Renaud descriptively only, and carries no implication as to age, though his own comparisons and the verdict of a number of distinguished European archæologists concur in seeing in these implements a close resemblance to the African races.

Measurement of Temperamental and Personality Qualities

REPORT No. 83 of the Industrial Health Research Board, by P. E. Vernon, is an account of the various tests that have been used to measure temperamental and personality qualities by means of rating scales and questionnaires, oral and written, but excluding the ordinary interview and clinical techniques. There is a short description of practically every published test within these limits, with an account of the method adopted, the statistical or other techniques used to evaluate the results, and a critical survey of the results and criteria. That a survey is necessary is implied by the surprisingly large number of the questionnaires in use, and by the fact that both in the medical and industrial field temperamental or emotional problems are proving to be urgent. Efficiency and even happiness in many walks of life are partly bound up with the temperamental make-up of the individual and some objective measure by which this could be assessed would be of great value. The conclusion of this painstaking study, however, does not permit of any belief that this at least by the means studied, is an immediate possibility. The author suggests that more care should be taken in compiling the tests and that investigators should not neglect the work of their predecessors. He gives a very clear discussion of the possibilities and drawbacks of this very popular verbal test.

Serological Reactions in Cancer Diagnosis

THE polarographic method developed by Prof. Heyrovský depends on the potential set up in a cell between a polarizable dropping mercury electrode and a non-polarizable reference electrode. The literature of the method and of its numerous applications is detailed in a comprehensive bibliography (Bibliography of Publications dealing with the Polarographic Method" by J Heyrovsky and J Klumpar *Coll Czechoslovak Chem Comm*, 10, No 2–3, pp 23, 1938), which covers the period 1922–37 Dr Brdička has applied this method to serological reactions, with special reference to cancer diagnosis ('Serologische Untersuchungen mit Hilfe der Polarographischen Methode und ihre Bedeutung fur die Krebsdiagnostik" by R Brdička, *Acta Internat Verein fur Krebsbekampfung*, 3, 13–30, 1938) Purr and Russel, and Waldschmidt Leitz, have produced evidence tending to show that in the blood of cancer patients there are relatively less sulphydryl groups than in normal blood The potential set up at the dropping mercury cathode, being a function of the reducing systems present, may be used to detect the amount of these groups in very small quantities of serum With this method, the author has investigated sera from 187 normal and pathological subjects, including cancer patients The cancer sera gave a diminished polarographic reaction, but this was also found in numerous inflammatory conditions, and is therefore not specific for cancer

Localized Nature of Photoperiodic Response

Dr W F Loehwing has recently published (*Proc Soc Exp Biol and Med*, 37, 631, 1938), the results of experiments in which the bases and tops of soybean plants were submitted to different photoperiods by training them to grow through a slit in a vertical opaque panel The plants were divided into three groups (1) controls with leaves and flowers intact, in one set of which tops were given long day and bases short day, in the opposite set tops were given short day and bases long day, (2) tops defoliated and bases exflorated, criss crossed as in controls, (3) tops exflorated and bases defoliated criss crossed as in controls The responses to differential lighting are clear cut Dr Loehwing concludes that the data indicate that the flowering stimulus is a foliar influence entirely distinct from carbohydrate synthesis The formative floral organization apparently depends upon one or more specific inductors the production of which in the soybean results from short day illumination Both the flowering stimulus of short day and its inhibition in long day exhibited a direct quantitative relationship to the amount of foliage The largest number of flowers on defoliated parts appeared on those plants with the greatest number of leaves under short day illumination

Protein Synthesis in Detached Leaves

In an extensive series of experiments on detached leaves of daffodils, *Pelargonium zonale*, *Iris Pseudacorus*, *Tropæolum majus*, *Ligustrum vulgare*, *Helianthus perennis* and *Vicia Faba*, W H Pearsall and M C Billimoria have shown, by floating the leaves on nutrient solution which allowed of rapid protein synthesis, that the capacity of leaves for protein synthesis under experimental conditions may depend upon their age, protein content and certain factors associated with the physiological condition of the whole plant (*Ann Bot*, New Series, 2, No 6, 317, April 1938) It is also suggested that the permeability of the dissolved solutes in the experimental medium may be an important factor The main significance in the results obtained is that it is probably undesirable to attempt to apply to other genera conclusions based on any one type of plant

Control of Michaelmas Daisy Wilt

Mr N C Preston has recently tested a method of control, originally suggested by W J Dowson, for the Verticillium wilt of the Michaelmas daisy (*Gard Chron*, May 14, 1938) The disease is caused by the fungus *Verticillium Vilmorinii*, which apparently does not extend into the smaller top shoots of an infected plant These can be struck as cuttings, and usually grow into disease free plants The malady appears to be rather widely distributed, and it is not always possible to obtain clean stocks for nursery propagation, hence the value of top cuttings as a practical means of multiplication of valuable strains, even though they be infected with the wilt fungus

Nature of Ultra-virus and Bacteriophage

A useful review of present day hypotheses about the nature of bacteriophage and ultra viruses is contained in a recent paper by Prof C Levaditi ("Les Ultravirus, *Bull Soc d Encour pour l Indus nationale*, 27–42, Janv Févr 1938) Prof Levaditi is scientific director of the Alfred Fournier Institute, and is in a good position to review the subject widely After considering the physiological similarity between bacteriophage and virus, he sifts the evidence for various theories as to their nature Are they inorganic, or unorganized organic matter comparable to enzymes are they organized living cells in the full sense of the term, or do they represent life laid down with illiberal autonomy ? Prof Levaditi inclines to the last mentioned view les ultravirus et les bactériophages paraissent appartenir a un monde vivant ignoré jusqu à ce jour ' The considerations are mainly illustrated by animal viruses, though plant viruses are also mentioned A good deal of modern knowledge is collected in the paper, and many interesting questions for future research arise from its perusal

Segregation in a Species Hybrid

By pollinating *Tragopogon pratensis minor* with pollen from *T porrifolius*, a hybrid was obtained by Dr O Winge (*C R* Lab Carlsberg Sér Physiol, 22, No 9) between two well known Linnæan species, one of which has yellow and the other violet flowers This cross was originally made by Linnæus himself and grown in 1759 The species also differ markedly in size of flower heads, foliage characters size of plant, achenes and pappus Both are found to have six pairs of chromosomes, but *T pratensis* has one pair of satellites while *T porrifolius* has two There are also differences in the size and constrictions of certain chromosomes The F_1 shows hybrid vigour but is highly sterile, producing only 8 per cent of good achenes in comparison with the parents Yet meiosis is regular Later generations were grown to F_7 and were much more fertile The F_1 were nearly uniform and intermediate between the parents Five independent pairs of segregating genes for flower colour were identified, but the ratios were frequently modified By selection in later generations, both parental species were obtained, with the corresponding chromosome morphology It is concluded that all the specific differences arose as genic differences in the chromosomes, and that there is therefore no absolute boundary between species factors and variety factors Two fine coloured plates illustrate the colours and other characters of the heads in the parent species and the various segregates

Tilting of the Ground at Wellington

In September 1930, an Ishimoto tiltmeter was installed at the Dominion Observatory Wellington in the hope that its records might lead to the prediction of local earthquakes The instrument continued in action until March 5, 1934 when it was broken by the severe earthquake of that day An account of the results obtained with its aid has now been published by Mr R C Hayes (*Dom Obs Bull* No 133, 625–628, 1938) The records showed marked diurnal and seasonal variations The diurnal tilt, sometimes exceeding 2 seconds follows the temperature variation, the curves of mean hourly tilt and earth temperature at a depth of one foot corresponding very closely The most interesting movement is a persistent westerly tilt of at least 10 seconds in less than 3½ years perhaps connected with crust displacements preceding the earthquake of 1934 With this possible exception, no connexion has been traced between the tilting of the ground and the occurrence of local earthquakes

Ultrasonic Dispersion

The technique used by Mr B V Raghavendra Rao of Bangalore in obtaining the preliminary results described in NATURE, (139 885, 1937) is given in full in a recent paper (*Proc Indian Acad Sci*, 7 Pt 3) The source of light was a cathode cooled, low density mercury lamp wave lengths 4046, 4078 and 4358 being used, 4078 in general proving most suited in spite of its low intensity The dust free liquids investigated were contained in a Wood tube and the fine structure of the radiation scattered backwards was examined by means of a Fabry Perot étalon the distance piece of which was chosen to suit each liquid For carbon tetrachloride using a 5 mm gap étalon, the author finds that while the velocity of ultrasonic waves of 1 1,000 megacycles per second is 920 m per sec that of hypersonic waves of more than 1,000 megacycles is 1 070 m per sec For acetone on the other hand, using a 4 5 mm gap etalon, the ultrasonic velocity is 1 205 and the hypersonic 978 m per sec For benzene and toluene measurements of hypersonic velocities have not proved accurate enough to warrant publication

Elements 43 and 61

A DISCUSSION of the possibility of the existence of stable nuclei of atomic numbers 43 and 61 is given by H Jensen (*Naturwiss*, 26 381, 1938) The importance of Mattauch's rule which states that if two isobares differ in nuclear charge by unity one of them must be unstable is emphasized and it is pointed out that the elements adjacent to element 61, ^{60}Nd and ^{62}Sm, have many isotopes This points to the fact that a nucleus with atomic number 61 would be unstable, and the same applies to element 43 The possibility that β active isotopes with these atomic numbers might exist and have very long lives, cannot be entirely ruled out, but is unlikely The existence of anomalies in the structure of certain nuclei is also mentioned Considering nuclei with odd mass numbers and only one isobare, the passage from one of these to the next is always accomplished (with four exceptions) by the taking up of either one neutron and one proton, or two neutrons, so that the atomic number only increases by 1 at the most Hence every chemical element must have at least one odd isotope The exceptions are the mass numbers 37 ($Z = 17$), 97 ($Z = 42$), 139 ($Z = 57$) and 145 ($Z = 60$) In these cases transition to the next nucleus of odd mass number is accomplished by taking up two protons so that the nuclei of atomic numbers 18 43 58 and 61 are passed over Nuclei with atomic numbers 18 and 58 do however, exist with even mass numbers On the other hand, the remaining two having odd atomic numbers (43 and 61) can have no isotope with an even mass number (owing to the rule that heavier nuclei with even mass numbers have always an even atomic number), and so should not exist at all

Polyphenol Oxidase

Keilin and Mann have recently described the preparation from *Psalliota campestris* of a highly purified polyphenol oxidase (*Proc Roy Soc* B 125, 187 1938) The enzyme contains copper as an essential constituent of its active group The less pure preparations contain large amounts of copper which, however does not belong to the enzyme, and no proportionality is found between copper content and activity until the copper is between 3 2 γ and 3 5 γ per enzyme unit At this level, the copper content and the enzymatic activity are strictly proportional The enzyme in its pure form has a high specificity Even when crude it oxidizes ortho dihydroxyphenols with great rapidity, but affects only a few monophenols such as *p* cresol As it is purified the enzyme gradually loses its power of catalysing the oxidation of monophenols

Constant of Nutation

DR H SPENCER JONES has recently published a paper (*Mon Not Roy Astro Soc* 98, 6, April 1938) on The Determination of the Constant of Nutation from the Greenwich Latitude Variation Observations in which he deals with the material available for the period 1911 36 from observations with the Cookson floating zenith telescope at the Royal Observatory Greenwich Dr J Jackson had previously utilized the observations from 1911 until 1929 to determine the constant of nutation from the latitude variations and while his method was closely followed certain minor alterations were introduced Amongst these may be mentioned the revision of the star places and proper motions, the application of corrections for wind and diurnal latitude variations and the reduction of morning and evening observations to identical epochs The value of the constant of nutation derived by Jackson was 9 2066″ ± 0 0055″, and that found by utilizing the results up to 1936 is 9 2173″ ± 0 0040″ The latter approaches much more closely the theoretical value than the former which presented a difficulty to Jackson he described the discrepancy as one of the outstanding discordances of the constants of the solar system By using Newcomb s formula, which connects the luni solar precession, the constant of nutation the mass of the moon and the mechanical ellipticity of the earth, the inferred value for the reciprocal of the mass of the moon is 81 53 This is based upon a luni solar precession for 1900 0 of 50 3899″ found by Newcomb, but according to Oort, who took into consideration the rotation of the galaxy, the value is 50 4012″ from which the inferred value for the reciprocal of the mass of the moon is 81 59 It is hoped that the observations of Eros at the 1931 opposition will provide a more accurate determination of the mass of the moon than that derived by Hinks from the 1901 opposition As a result, the nutation constant should be found with greater accuracy

Cambridge Meeting of the British Association

Sectional Programmes

SECTION A (MATHEMATICAL AND PHYSICAL SCIENCES)

THE programme of Section A, as seems appropriate at Cambridge, is less concerned with applied physics than has been the case for a year or two. The opening morning is devoted to a symposium on nuclear physics, in which Niels Bohr and W Bothe will represent the Continental workers On Friday, after the presidential address, the Section will divide into two, one part discussing the fundamentals of magnetic theory and the other hearing three papers on subjects of astronomical interest The first, by Shapley, is on the galaxy, the second is by Ives, and deals with his recent experiments in which the theory of special relativity receives direct support from experiments on the light emitted by positive rays, and the third is an account by R W Wood of the new diffraction gratings, which have so improved the technique of astrophysical work with spectrographs The Saturday morning will find the Section at work on problems of cosmic rays, with an American and a German guest, in the persons of Prof Furry and Prof E Regener In the second week come symposia on low temperature (particularly that queer material, liquid helium II), and on seismology, the latter taking place at the same time as a further discussion on magnetism, this time jointly with Section G (Engineering)

Those who have missed the general excursions by attendance at the meeting on Saturday will find consolation in the fact that the Section dinner, to be held for the first time, is booked for that evening, they may fill in the afternoon at a garden party in the Observatory Other visits during the week are to the works of the Cambridge Instrument Co, Ltd, and to the Cavendish and Mond laboratories, where a film of solar prominences will be shown, and a record of the voice of the late Lord Rutherford will be heard

THE Department of Mathematics has a programme which is exceptionally attractive mathematically Among the visitors expected are Prof. G D. Birkhoff, Prof. S Lefschetz, who will lecture on the fundamental problem of fixed points in topological transformations, Prof A. Ostrowski, bringing a modification of Newtonian approximation, and Prof A Speiser, looking at elliptic functions from the point of view of elementary geometry The theory of groups and topological algebra are represented further by Mr P. Hall, Dr. B H Neumann, Dr O Taussky and Mr J H C Whitehead, as well as by Mr M H A Newman, who is to speak on the topological characterization of the sphere in n dimensions, a problem which goes back to Poincaré Prof. W V. D Hodge and Mr B. Kaufmann have contributions on geometry and analysis, and Prof E H Neville and Mr D H Sadler will follow Prof Ostrowski

The Association's Committee on the Calculation of Mathematical Tables, acting through Dr. W. G. Bickley, Dr J C P Miller and Dr A. J. Thompson, will take members behind the scenes to look at some of the problems, mathematical and typographical, that come between the simple decision to tabulate a function and the appearance of the printed volume. The National Accounting machine used by the Committee for sub-tabulation and the preparation of printers' copy is to be brought from London for inspection and demonstration, with an operator to explain the adaptations and ingenuities which have effected its conversion from commerce to pure science Explanations and demonstrations will be given also of a number of other machines, including a model of the Bush integrator, the Mallock equation-solver and Hollerith and other machines; in this exhibition the companies concerned are co-operating with the Association Interest in the practical side of computation has been expressed and stimulated at Cambridge by the establishment of a mathematical laboratory, and a visit is planned to this embryonic institution

Lastly, the application of methods and ideas of combinatorial analysis to the planning of biological experiments will be explained in a series of papers by Dr C C Craig, Mr H W Norton, Mr W L Stevens, Mr. F Yates and Dr W J. Youden.

SECTION B (CHEMISTRY)

The president, Prof C S Gibson, in his opening address, will review the recent advances that have been made, chiefly by himself and his co-workers, in the chemistry of gold. This will be followed by a discussion on the recent advances in the organic chemistry of the metals with special reference to the noble metals, in which the principal speakers will be Dr. F G Mann, Prof L O. Brockway (Pasadena) and Prof N V Sidgwick Attention will be directed mainly to the electronic and stereochemical aspects of the subject In the afternoon, Prof Gibson, with the assistance of Dr F. G Mann, Mr. H. V. Thompson and Dr F. H Brain will give a demonstration on the production and application of gold films by ancient and modern methods The processes employed in the ceramic industry and methods depending on the decomposition of organic compounds of gold will be demonstrated. Many specimens will be on exhibition The demonstration is arranged to be of general rather than purely sectional interest

A discussion on modern methods of chemical analysis, including physical and microchemical methods, will be opened by Dr. J. J. Fox, Government Chemist. Contributions will be made by Prof Walther Gerlach (Munich), Prof. Fritz Feigl, Dr Janet Matthews, Dr. H Jackson and Dr K K Nygaard (Oslo)

Prof. W. L. Bragg will open a discussion on "Clays". He will be followed by Dr R. K. Schofield, Dr Nagelschmidt and Prof. J. D Bernal The speakers will deal with the atomic architecture of clay and clay like minerals, with the origin of the electric charges on clay particles, with base exchange, the absorption and yielding up of water and the behaviour of clays in soils.

The fourth symposium of the meeting, entitled "Repercussions of Synthetic Organic Chemistry on Biology and Medicine", which has an added interest in view of the exceptional circumstance that the Physiological Section will not meet this year is being arranged by Prof E C Dodds and Prof J W Cook Recent work on the production of new compounds having the biological action of the sex hormones will be described by Prof Dodds and Prof L Ruzicka (Zurich), and Dr A S Parkes will deal with some of their interesting biological interrelationships The second half of the programme will be occupied with descriptions of synthetic compounds which are able to induce cancer (Prof J W Cook) of new compounds having the physiological action of the life maintenance hormone of the adrenal cortex (Dr T Reichstein, Zurich) and of the synthesis of vitamin B_1 and analogous compounds (Prof A R Todd) Specimens and apparatus relating to these discussions will be on exhibition throughout the meeting

By the kind invitation of Sir William Pope a visit will be made to the University Chemical Laboratories Sir F Gowland Hopkins has also kindly invited the Section to visit the Departments of Biochemistry and Parasitology Visits will be made to the Cambridge Instrument Co , Ltd , and Messrs Stewarts and Lloyds' steel works at Corby

The sectional dinner will be held in Sidney Sussex College by kind permission of the master and fellows The following chemists have accepted the Council's invitation to attend as foreign guests of the Association Prof G Bertrand Paris , Prof L O Brockway Pasadena Prof Fritz Feigl , Prof Walther Gerlach Munich , Dr T Reichstein Zurich , and Prof L Ruzicka Zurich

SECTION C (GEOLOGY)

Up to the delivery of Prof H H Swinnerton's address on Development and Evolution the interest of the programme of Section C is mainly on the stratigraphical and palæontological side After the address the petrological side dominates

The post glacial history of the Fenlands is to be considered jointly with Section K (Botany) Short papers dealing with levels and benchmarks archæological correlations, conditions in Roman times and the Foraminifera in the deposits will provide the basis around which the discussion can range

A more specialized subject is The Distribution and Migration of Certain Animal Groups in the British Lower Palæozoic Fauna Dr C J Stubblefield will open and deal with the Trilobites, and Dr G L Elles on Graptolites, Dr W K Spencer on Starfishes and Dr A Lamont on Brachiopods will follow With such experts on these particular groups important points in *palæogeography may emerge*

The association and origin of alkali rich igneous rocks with limestones has long been of considerable petrogenetic significance This time the question is to be debated from the opposite angle The Origin of the Carbonate Rocks associated with Alkali Rich Intrusions Dr H von Eckermann of Sweden will open the discussion

Water supply matters are very much to the fore at the present time Dr J Buchan in dealing with the underground supplies of London will show that the progressive lowering of the water level there is giving rise to concern about the life of the supply This lowering, also, is leading to a deterioration in quality due to the drawing in of contaminated surface waters

Among the papers to be given, those concerning some peculiar leucite rocks from Australia the granites of the Egyptian desert the palisade diabase sill of New Jersey and the occurrence of zonal olivines should be of considerable interest

SECTION D (ZOOLOGY)

Section D (Zoology) will be presided over by Dr S W Kemp whose presidential address will deal with the future of oceanography

The item in the programme of the Section which will perhaps arouse the most general interest is a discussion on the mechanism of evolution extending over a whole day The range of the discussion will cover such aspects of the subject as the importance of character gradients selection orthogenesis consequential evolution polymorphism and isolation as factors in the evolutionary process The speakers include Prof J S Huxley Prof R A Fisher and Prof A E Trueman

Prof J Gray will introduce a discussion on the role of the environment in animal locomotion and the papers which follow will treat mainly of the work of the Cambridge school in the analysis of locomotion in aquatic terrestrial and aerial forms of life A symposium on sense perception and the evolution of colour and pattern will be introduced by Prof J S Huxley and contributions from Dr H B Cott Mr D Lack and Mr I Burkill will treat of the subject from the point of view of protective coloration the courtship of birds and the correlation between insect vision and flower colour respectively

Dr H C Gilson is to give a semi popular lecture on the recent expedition to Lake Titicaca

There will again be an exhibition of biological films of educational interest These will include two films produced by the Strand Film Co , Ltd , on mites and monsters and monkey to man shown by Prof J S Huxley, and films produced by Gaumont British Instructional Films Co Ltd on the liverfluke the crayfish, and the development of the trout shown by Mr H R Hewer An excursion to Wicken Fen and Breckland is included in the programme of the Section for the Saturday of the meeting

SECTION E (GEOGRAPHY)

The programme for Section E will be opened by the president, Prof Griffith Taylor, who proposes to deal with geography as an aid to social problems, history and race His address will be followed by a number of short papers and a film dealing with the impressions of geographers during the recent visit of the Association to India

On Friday there will be a series of local papers, including two lectures preparatory to the excursions on Saturday and Sunday Of these latter the first will be to the north Norfolk coast, while the second will visit the Fens Monday is to be given over largely to a consideration of the physical factors affecting English ports and estuaries and will include a visit to the Great Ouse Catchment Board

On Tuesday morning a sectional discussion on Some Aspects of the Regional Concept' will be opened by Dr S W Wooldridge, while in the afternoon two papers will discuss some particular features of population distribution On the last morning Dr Vaughan Cornish will continue his plea for the preservation of coastal scenery, this time at Sidmouth, and Brigadier Macleod will discuss the Departmental report on the Ordnance Survey

Among individual contributions not already mentioned may be instanced a discussion on the geographical laboratory, to be opened by Prof F Debenham an account of some of the discoveries of the recent Graham Land expedition by Mr Bertram, and some further results of his work on cirque formation by Mr W V Lewis The programme includes a much larger number of short papers than usual and by reason of its wide field should offer many items of interest to members of other sections

SECTION F (ECONOMICS)

The programme of Section F is very largely given up to the discussion of current matters of public importance and with the development of statistical and other methods for investigating them

There will be three papers by Sir William Beveridge Mr D Champernowne and Mr R C Tress on various aspects of unemployment in relation to the trade cycle its connexion with the local diversity of industry and its recent trends The statistical methods of testing trade cycle theories and of measuring the mobility of labour are being discussed by Prof Tinbergen and Dr Marschak of the Institute of Statistics Oxford, respectively Other topics of current importance under discussion will be public works policy in the trade cycle the economics of road haulage since the Road and Rail Traffic Act of 1933 and the economic recovery of Germany Mr J M Keynes has promised a paper on The Problem of Government Storage of Food Stuffs and Raw Materials

Mr R F Harrod the president is speaking on The Scope and Method of Economics a topic which should be of interest in relation to contemporary developments and controversy The Section has also made arrangements for a discussion of papers on general sociological questions, by Mr T H Marshall on Professionalism ' and Prof M Ginsberg on The Present Position of Sociology'

SECTION G (ENGINEERING)

In his presidential address Prof R V Southwell will deal with the Changing Outlook of Engineering Science

There will be a group of papers on problems of vibration, opened by a short paper and demonstration given by Prof C E Inglis There will be another group of papers dealing with problems in connexion with magnet steels Major Cook, chief engineer of the Ministry of Transport, will open a discussion with an important paper on the design of roads

An innovation of great interest is the experiment of including ten short papers by junior engineers who will describe work with which they are intimately connected Each paper and its discussion will occupy no more than thirty minutes The meeting will conclude with a lecture and demonstration of engineering instruments given by Mr Mason of the Cambridge Instrument Co , Ltd

SECTION H (ANTHROPOLOGY)

The anthropological programme is unusually full, and it has been necessary to arrange several parallel series of lectures On Thursday morning there will be a general discussion on the Australian aborigines, and a film, recently taken by Dr Donald F Thomson, will be shown in the new Arts Theatre In the afternoon papers will be read on local archæology in preparation for the excursions on the Saturday and Sunday

Friday is given up to two symposia the topic for the morning meetings is the Swanscombe skull and for the afternoon, the Middle Palæolithic In both symposia papers will be read on the geology skeletal remains and human artefacts The presidential address will be given on Monday morning by Prof V Gordon Childe, and Miss Caton Thompson and Miss Gardner will describe the results of their recent expedition to South Arabia In the afternoon Sir Arthur Keith will speak on the Mount Carmel skeletons and on a reconsideration of the Piltdown skull Other papers will also be given on Cypriote skulls the stability of English rural population and on natural selection

There will be a number of papers on folk culture on Tuesday morning and in the afternoon four papers on ritual —ritual and emotion, ritual and tradition, ritual and myth, and ritual and magic General ethnology will also be represented by a number of contributions on Cambridge, Lapland West Africa and Zanzibar and by papers on boats primitive art currency, and on sign language

SECTION I (PHYSIOLOGY)

The International Physiological Congress is being held at Zurich on August 14–19 it has therefore been decided not to hold meetings of Section I at Cambridge

SECTION J (PSYCHOLOGY)

Section J (Psychology) has a very full programme The presidential address to be delivered by Dr R H Thouless is entitled Eye and Brain as Factors in Visual Perception

Roughly grouping the other topics there are papers on social psychology covering the social implications of vocational guidance friendliness and unfriendliness between different social groups, generalized foreign politics (this last a mathematical analysis) and problems of the social psychology of childhood General psychology is being dealt with in papers on present trends in American psychology and on hormic psychology while merging into things therapeutic we get problems of the mature personality, the background of the problem child the teaching of mental hygiene through literature with a turn towards heredity in papers on heredity and mental hygiene and the inheritance of temperament respectively

Dealing more with the experimental side are papers on motor learning and the morphology of responses, the direction of thought a curious pitfall in factor psychology, verbal problems connected with the definition of personal qualities, factors affecting the reliability of interviews, behaviour when attempting difficult tasks, sensory adaptation (in vision and hearing) and colour blindness Animal psychology is represented by a paper on recent experiments with birds, while there is a joint session with Section L (Educational Science) on the influence of wireless and the cinema on education

SECTION K (BOTANY)

The botanists and foresters who gather at Cambridge may anticipate an interesting meeting, for a full programme is in prospect The president, Prof W Stiles, will open the proceedings with his address on the general physiology of the plant cell This will be followed by the address of the chairman of Department K*, Sir Roy Robinson who will speak on the supply of home grown timber

A number of joint meetings have been arranged Sections C and K will unite in a meeting on the post glacial history of Fenland in which botanical geological and archæological matters will be discussed A meeting of Sections D and K, spread over two sessions, will be concerned with the mechanism of evolution a subject which should provide abundant argument both formal and informal Botanists and foresters will consider together the relation of ecology and forestry

A group of contributions on the virus diseases of plants, followed by a discussion, will indicate the present position of this important branch of plant pathology

In addition to the selected subjects which have been mentioned, many separate communications will be presented These include series of papers on plant physiology, mycology and palæo botany and others on genetics morphology and ecology

The foresters (Department K*) in their separate meetings, will devote three sessions to a consideration of the cultivation and utilization of British hard woods and a further session to soil problems and to pathology

Prof A H R Buller will deliver the semi popular lecture he will speak on sex in the rust fungi

An extensive display of exhibits will illustrate many aspects of botany It is expected that much of the material will be on view during most of the week and during one afternoon session, exhibitors will give demonstrations and explanations

Excursions to places of interest to botanists and foresters will take place during the meeting the principal excursions falling on Saturday and Sunday

SECTION L (EDUCATIONAL SCIENCE)

The greater part of the Section's programme as in recent years, will be devoted to one or two main subjects , the principal theme for 1938 is Education for a Changing Society The speakers on this theme will examine to what extent the education given in the senior, secondary and technical schools aims at preparing their pupils to meet the complex needs of the rapidly changing world of to day Miss Dawson of Middlesbrough and Mr Robinson of Sheffield will speak as heads of senior schools, while Miss Davis of Streatham and Dr Freeman of Winchester will discuss the contribution of secondary schools Mr Paley Yorke of Poplar, Dr Richardson of Derby and Mr Frank Pick of the London Passenger Transport Board will analyse the part played by technical education, and Dr Winifred Cullis will represent the point of view of the universities

Another outstanding item will be a symposium on Thursday on "Tendencies in School Design", when papers will be read by Mr S Urwin of Cambridge, Mr Denis Clarke Hall and Mr W G Newton of London and Mr W D Seymour (In connexion with this subject there will be an exhibition of school models and designs by courtesy of the Royal Institute of British Architects) A joint session will be held with Section J (Psychology) on the influence of films and wireless on the education of the school child, Mr R C Steele of the B B C and Dr P B Ballard speaking for Section L

The president, Mr J Sargent director of education for Essex will deliver his presidential address on Friday taking as his subject the Function of the Administrator The interim report of the Research Committee on the Informative Content of the Curriculum will be presented at the same session by Mr H G Wells and Sir Richard Gregory

SECTION M (AGRICULTURE)

The general theme for all the paper reading sessions of Section M is Agriculture in Relation to the Life of the Community On the Thursday morning there will be a symposium on Agriculture in Relation to National Employment Prof C S Orwin will open this and will deal in general with the demands for labour in agriculture He will be followed by Prof Scott Watson who will consider the influence of systems of farming on labour requirements by Mr S J Wright who will speak on Men and Machines (including transport on the farm) and by Dr F Kidd who will deal with the Preservation Storage and Transport of Farm Produce There will be a general discussion opened by Prof R G White

On Friday morning Prof R G Stapledon will give his presidential address entitled Ley Farming and a Long Term Agricultural Policy This will be followed by two papers on soil problems namely Problems of Marginal and Waste Land by Dr W G Orr and The Maintenance of Soil Fertility by Dr E M Crowther The general discussion will be opened by Sir Daniel Hall

Monday morning will be devoted to a consideration of The Practical Problems of Crop Production in which Mr J A McMillan will deal with crop husbandry Prof F L Engledow with the place of plant physiology and of plant breeding in the advancement of British agriculture and Mr C T Gimingham with crop pests and disease Sir John Russell will open the general discussion which follows

On Tuesday morning there will be a symposium on The Practical Problems of Animal Production Prof R Rae will open this with a paper on animal husbandry He will be followed by Prof F A E Crew who will speak on animal breeding, and by Dr E L Taylor, who will deal with parasitic diseases in animals

CONFERENCE OF DELEGATES

The Conference of Delegates of Corresponding Societies will be presided over by the Right Hon the Earl of Onslow and among the principal subjects to be considered are some of wide and national importance Lord Onslow in his address will deal with The Importance of National Parks in the Preservation of the Flora and Fauna of Great Britain while the urgent desirability of the preservation of Crown lands will be especially referred to by Dr Vaughan Cornish

Another subject of more than local interest is that of Wicken Fen and what the National Trust has done for East Anglia, upon which Mr N B Kinnear and Dr M F Valentine will speak

The problem of obtaining periodical and simultaneous field observations over wide areas upon such matters as bird and insect migrations, the prevalence and distribution of wild plant and animal communities both harmful and beneficial and the effects upon these of the widespread planning and industrial development of recent years is becoming a matter of significant importance in biological studies, and the co operation of the corresponding societies in the study of systematics in relation to general biology, which will be discussed in a communication from Mr H W Parker should prove of assistance and value in effectively ascertaining the desired information by co ordinated field observations upon specific subjects

An innovation will this year be introduced at Cambridge when the delegates of the corresponding societies and their guests will dine together, Lord Onslow presiding They will also attend an afternoon garden party at the Cambridge Botanic Gardens as the guests of Prof F T Brooks The view has been expressed that the business of the Conference affords insufficient opportunity for that social contact which is considered desirable and can best be attained by such functions

National Efforts in Cancer Treatment

THE eighth annual reports of the National Radium Trust and Radium Commission, 1936 1937 (published in December 1937)* is of special interest in that it breaks away from the immediate task which confronted it in 1929 and now seeks to guide activities on a broader basis The following paragraph taken from p 23, illustrates this

'The Commission believes that to secure a reasonable standard of service for the treatment of cancer cases throughout the country there is need for the whole problem to be attacked by the Government along national lines This belief is supported by the fact that only a proportion of patients suffering from cancer in sites suitable for treatment by radiotherapy are receiving that treatment

With the resources initially placed at the disposal of the Trust and the Commission, it was decided that a practical beginning to the problem of using radium in the treatment of disease could best be obtained in the way the Commission strove, namely, to secure *so far as possible the concentration of radium treatment* at the large voluntary hospitals which provide teaching facilities It was inevitable that this left large parts of the country unprovided with radium facilities, and in consequence centres other than the national centres were set up so that a glance at the map provided on p 2 of this report shows 13 national centres, 9 regional centres and one recognized hospital where the Commission has its immediate interests

In the report for the preceding year, the National Radium Trust, in looking to future needs stated that The views of the Radium Commission as to the need for further considerable supplies of radium have received and are receiving anxious consideration the more so as it seems clear that with the trend towards the use of larger units the ultimate need over the next few years will be far beyond the financial resources of the Trust The Commission now sees this whole problem of the radiological treatment of cancer looming larger with each succeeding year

This may occasion little surprise to those who have witnessed at close range the developments of radiological treatment especially in cancer, but it may well be different for those who, with the constant reminder of cancer statistics in front of them, may question how valid is the warrant for any big extension of these services The fact is that surgical and radiological methods of treatment are the only two methods which are practised on any scale in Great Britain, and with a death rate not far short of 60,000 people yearly, it is really an urgent matter to make the most of what we have got Thirty years ago it was not unusual for people to exclaim as to how gladly money would be given for a cure for cancer It has not been claimed in any one of the reports which have been issued from the Radium Commission that radium treatment is a cure for cancer, but it is claimed, and supported by the most carefully gleaned (not selected) statistics that large numbers of cancer patients have been treated with radium and have successfully survived periods of five years Since cancer is likely to recur in the body it is generally held to be unwise to use the term cure, but 'freedom from the disease is a term which is accepted on a clinical basis, and the survival rate' is one which is of the first importance in adjudging the value of any remedial measure

To return to the belief expressed by the Commission that the treatment of cancer is a problem to be attacked by the Government This is shared by many people, but the steps by which it could be carried out have never been laid down, and are but hinted at in the report in question The Commission does, however, state that an increase of bed accommodation at or in association with the existing *national centres* will be required The words "at or in association with suggest and are probably intended to convey, that any such scheme could only be carried out with the active co operation possibly the direction, of the Ministry of Health It is, in fact, very difficult to see, with the pressure upon the bed accommodation of voluntary hospitals all over Great Britain, how any large increase in treatment facilities could occur without very extensive building and staffing The position is indeed one which calls for the most sympathetic consideration by the Ministry, because by far the greater proportion of radium therapy carried out at present is done at the voluntary hospitals, the part played by those under the direction of the Ministry being, in fact, relatively small though doubtless locally very important If, then, the best that we can offer in the way of treatment for cancer can only be shared by the whole country by the operation of some comprehensive scheme such as that outlined by the Commission, it is a plain duty to be undertaken

It has been pointed out more than once that the first need of the population is to be fed, the second is to be housed, the third (perhaps) is to be educated. Then comes the question of fitness in health, and unfitness through ill health It may well be that the claims of the treatment of people suffering from cancer may be dislodged from the official mind by the claims of the really healthy, that money should first be spent on the attainment of physical fitness rather than on the relief of the sick

S RUSS

Science News a Century Ago

Frédéric Cuvier, For Mem R S (1773 1838)

Frédéric Cuvier an eminent French naturalist and younger brother of the more celebrated Baron Georges Cuvier, was born at Montbeliard on June 28, 1773. At his brother's suggestion he went to Paris in 1797, where he attended lectures on physics, chemistry and natural history. In 1802 he became chief editor of the *Journal de la Société d'Encouragement pour l'Industrie Nationale* and was entrusted by his brother with the compilation in collaboration with Duvernay of the catalogue of the animals in the Jardin des Plantes commenced by Buffon and Daubenton. In 1804 he became director of the Jardin des Plantes, where he made some valuable observations on the economy and physiology of the animals, which were published in the *Annales du Muséum*. In 1824 appeared his chief work, written in conjunction with Geoffroy St Hilaire, entitled Histoire Naturelle des Mammifères, in which more than five hundred quadrupeds were carefully described. He also published a large number of zoological articles in the Dictionnaire des Sciences Naturelles and the volume on Histoire des Cétacées in Suites de Buffon. In 1831 he was appointed inspector general of the Academy, and in 1837 professor of physiology at the Paris Museum of Natural History. He died on July 17 1838.

Early History of Embryology

In a retrospective address delivered at the sixth anniversary meeting of the Provincial Medical and Surgical Association held at Bath on July 18 19 1838, and published in the *Transactions* of the Association Dr Jonas Maldon senior physician to the Worcester Infirmary, made the following remarks: Embryology or that department of anatomy which traces the gradual development of an animal (more particularly of man) from the early stage of intra uterine existence until it arrives at its perfect formation, is a branch of anatomy almost unknown in this country although during the last twenty years it has been investigated with great success on the Continent. It is to the labours of the French and German anatomists, more especially those of Meckel and Tiedemann, of Geoffroy St Hilaire and Serres that we are indebted for almost all we know upon this interesting subject. Their researches have made known to us the wonderful truth that the intra uterine being passes through a series of successive changes of existence, beginning with the most simple state, and gradually advancing to the more complicated and perfect. They have shown us that the human embryo at the earliest period of its evolution is analogous to some of the simplest members of the zoophytic class, being nothing save a mere vesicle or globule, filled with a glairy fluid, and exhibiting no appearance of variety of parts, and that, gradually, organ after organ, and system after system, are developed, and more and more completely formed, each successive change representing as it were the structure and formation of an animal higher and higher in the scale of organization."

Death of Pierre-Louis Dulong, For Mem R S

On July 19, 1838, the eminent French chemist and physicist Pierre Louis Dulong died in Paris at the age of fifty three years. He was born at Rouen on February 12, 1785. In his sixteenth year he entered the famous Ecole Polytechnique in Paris in which he afterwards was given chairs of chemistry and physics and held the post of director of studies. In early manhood he appears to have practiced medicine for a time treating poor patients free but attracted by the discoveries of Davy and others he devoted himself to chemistry and worked in the laboratory of Berthollet. When twenty six years of age he lost an eye through an accident with nitrogen chloride. Much of his work was done in collaboration with his colleague Alexis Thérèse Petit (1791 1820). Together they made elaborate experiments on mercury and air thermometers in 1817 they published a memoir on the rate of cooling of bodies, which was crowned by the Paris Academy of Sciences and in 1819 they enunciated the law bearing their names, connecting the atomic weight and specific heat of a solid. On Petit's death in 1820 Dulong succeeded to the professorship of natural philosophy at the Ecole Polytechnique in 1823 he was elected a member of the Academy of Sciences and nine years later was made one of the permanent secretaries. Some of his later researches related to the elasticity of high pressure steam afterwards studied by Regnault.

University Events

Belfast. The degree of D Sc *honoris causa* has been conferred on Prof J P Hill professor of embryology Department of Anatomy University College London.

Cambridge —H B Cott Selwyn College and Dr J E Smith (London) have been appointed University lecturers in zoology and Dr V J Chapman Gonville and Caius College University demonstrator in botany.

Prof F T Brooks has been appointed a governor of the National Fruit and Cider Institute until June 13 1941.

The Benn W Levy Research studentship in biochemistry has become vacant. Applications for its tenure should be addressed to Sir F Gowland Hopkins at the School of Biochemistry before July 16.

The Board of Management of the Frank Edward Elmore Fund will shortly proceed to the award of a studentship for research. The studentship is open to male graduates of any university in any country who were born at any place within the British Empire other than Scotland. The Student appointed will work in the Department of Medicine of the University of Cambridge under the direction of the regius professor of physic. The commencing salary will be £300 a year and the appointment will be for two years in the first instance. Further information may be obtained from the Regius Professor of Physic, Department of Medicine University of Cambridge, to whom applications, together with three testimonials, a statement of previous appointments, and copies of published papers, should be sent not later than August 1, 1938.

At Sidney Sussex College Dr R A McCance, formerly research student of the College, University reader in medicine, has been elected to a fellowship.

London —Dr F A Paneth has been appointed, as from October 1, to the University readership in atomic chemistry tenable at the Imperial College Royal College of Science. Since 1933 he has been a consultant of Imperial Chemical Industries, Ltd, and has been engaged in research work with post graduate students at the Imperial College.

Edinburgh

Royal Society, June 6

Enid Charles Differential fertility in Scotland, 1911 1931 (1) Tables were presented giving gross reproduction rates in 1911 and 1931 for the counties of Scotland, for the total small burghs and landward areas in each county and for the large burghs and cities Between 1911 and 1931 the range of fertility in Scottish local areas has contracted and the percentage fall has been greater where initial fertility was higher The highest current fertility is found in the Clyde industrial area and in some relatively prosperous agricultural regions The lowest fertility is found where the textile industry is important and in some of the crofting counties

R M Neill Food and feeding of the brown trout (*Salmo trutta* Linn) in relation to the organic environment A detailed quantitative study of the invertebrate population of a defined river area and of the food of trout therein The range of the trout's diet —the potential range of which is controlled by the physical environment—is indefinite, covering all the co existing fauna of its habitat Species are fed on to an extent depending on their degree of accessibility and the extent of their representation in the fauna This is sufficient to account for the nature of stomach contents without invoking discrimination on the part of the fish

V Tchernavin Malformations in the adult salmon as a key to the understanding of the fate of smolts during their sojourn in the sea A detailed examination of two salmon with injured opercula shows the disturbances to be more deep seated than apparent externally The operculum preoperculum suboperculum and branchiostegal rays are considerably involved and in one of them the chondrocranium also The gills on the injured side are much reduced From a consideration of these and other malformations not infrequent in salmon coming in to spawn the author concludes that the enormous loss of smolts in the sea is due to periodical catastrophes Further, that these periods are of short duration and are not the result of a struggle for existence as usually understood

J A Moy Thomas and **Bradley Dyne** The actinopterygian fishes from the Lower Carboniferous of Glencartholm Eskdale, Dumfriesshire The actinopterygian fauna of the Lower Carboniferous of Glencartholm Eskdale Dumfriesshire, has been re examined and the general anatomy of these forms redescribed with particular reference to the dermal skull bones *Rhadinichthys fusiformis* was found to include *Rh angustulus* and the Glencartholm specimen of *Elonichthys striatulus* Three species, *Mesopoma pulchellum* *M politus* and *M crassum* have been separated from the genus *Canobius* Two new genera, *Paramesolepis* and *Proteurynotus* have been erected The nature of the bones of the snout region in palæoniscids is discussed and it is concluded that the premaxillary of teleosts is absent in the majority of Palæoniscids

E M Anderson Dynamics of sheet intrusion, with some considerations on faulting Use is made of C E Inglis's formulæ for the stresses surrounding plane cracks, in a solid under tension These can be applied, with slight modifications, to the case when the crack is filled with fluid under hydrostatic pressure

Gunnar Dahlberg Rare defects in human populations with particular regard to the inbreeding and isolate effects A suggested way of decreasing rare recessive defects is prevention of cousin marriage In a large isolate, there are not many cousin marriages In a small isolate on the other hand, there may be many cousin marriages but there cannot be an infrequent gene These factors are balanced so that the effect of preventing first cousin marriages is a decrease of the very rare defects with a maximum of 30 per cent but, in practice, the figure is expected to be, and is, about 15 per cent Another mechanism which may decrease the frequency of rare recessives is crossing over boundaries of pre existing isolates The frequency of cousin marriages in Germany has decreased from 0 70 per cent to 0 20 per cent in the last fifty years From this is to be drawn the conclusion that isolates are more than doubled through crossing over their former boundaries This must have decreased the frequency of rare recessives to less than half its former values This process has brought about an increase of heterozygotes and a decrease of homozygotes

Paris

Academy of Sciences, May 23 (C R 206 1517 1600)

Alexandre Guilliermond and **Roger Gautheret** Observations on the action of various colouring matters on living plant cells Plant cells are permeable to acid colouring matters under special conditions, whilst basic colours penetrate easily Some fix themselves easily on the cytoplasm and the nucleus and these are the most toxic Others less toxic colour both the cytoplasm and the vacuoles The least toxic, such as neutral red accumulate exclusively in the vacuoles

Co-operation in World Affairs

THE annual reports in which the Director of the International Labour Organization surveys world industrial conditions owe their exceptional value not only to the large resources of knowledge upon which they draw their wide outlook and measured but unequivocal judgments but also to the admirable way in which Mr H B Butler avoiding excessive occupation with the detail of the work of the Organization has given a balanced estimate of tendencies and changes in the economic and industrial situation for which the scientific worker no less than the economist or statesman should be grateful Mr Butler's latest and last report* is no exception and his review of current conditions is followed by an appreciation of the changed distribution of economic power in the world which should facilitate judgment as to the extent or severity of the recession in trade

On the purely economic side Mr Butler is indeed fairly hopeful Notwithstanding the continued political unrest and the hindrances deliberately put in the way of international trade the world has struggled back to a prosperity which if anything surpasses the level of well being in 1929 In spite of the severity of the American depression he anticipates an early resumption of activity and sees some signs of greater international co operation in trade and in currency matters

This optimism is however restrained and against this prosperity Mr Butler sounds two notes of warning First the present is an unstable prosperity and in part issues precariously from vast expenditure on armaments and the outlay of borrowed money Peace as well as prosperity depend largely on international trade The effort of nations to live more and more to themselves the pursuit of policies which make it imprudent to be dependent on other countries for essential supplies and consequent disengagement so far as possible from a world economic system—these all menace such comparative prosperity as we still enjoy While the energies of every great nation are primarily devoted to war economic development encased in a military strait jacket and social welfare subordinated to the construction of guns warplanes and battleships expectation of the future must be tempered with anxiety rather than hope

Secondly Mr Butler contrasts what prosperity at present exists with what might be enjoyed in a different atmosphere It is certain that genuine prosperity might have been more abundant and the prospects of endurance greater had not an excessive portion of the wealth of almost every country been diverted to war purposes As the International Chamber of Commerce recognized at Berlin last year in all countries the rapid progress of science and invention and modern methods of production and transport would permit of the standards of living being greatly improved provided the world would co operate in rational distribution In an atmosphere of autarchy or national competition there is no prospect of attaining the standard of feeding clothing health housing working hours or leisure which the vast technical progress of this century has brought within our grasp

It is well therefore to be reminded by this sober review that in spite of all the national experiments, many of which have achieved a considerable measure of success a high standard of living cannot be achieved by national effort alone No country can realize its full economic and social potentiabilities except as a part of the world community Failure to recognize this truth is not merely the gravest threat to prosperity everywhere The progressive subordination of the whole national life and the activity of every individual to the requirements of the State the cramping and distortion of individual freedom and economic expansion are already blocking some of the main lines of social advance and now threaten to sap the social edifice which this generation has raised

---

*International Labour Office Twenty fourth Session Geneva, 1938 Report of the Director Pp 81 (Geneva International Labour Office) 1s 6d paper 2s 6d cloth

The sombre picture which Mr Butler gives is one which requires careful consideration by all thinking men including scientific workers as such Only by a determined effort can the present progressive deterioration be averted and that effort is now demanded in the interests of science itself Moreover though science cannot take more than a small part of the blame for mankind's failure to utilize scientific knowledge to the fullest advantage in service of man's daily needs or for the use of scientific knowledge for destructive purposes scientific workers are also citizens and as such must accept the greater responsibilities which their knowledge and training entail

It is not of course within the scope of Mr Butler's report to suggest ways and means of securing action He can only give a warning and it is one to be heeded by scientific workers Moreover the report is not without certain suggestions which merit their special attention In discussing the question of unemployment Mr Butler points out that although in most countries the employment situation was much better in 1937 than at any time since 1929 due partly to demands for war material and the expansion of armed forces there is in many countries a marked shortage of skilled workers This is due partly to military requirements but mainly to the failure to educate a sufficient number of apprentices during the depression Accordingly it is suggested that the whole question of industrial education and training for industry should be reconsidered

This is a question with which scientific workers are very closely concerned Even in regard to the problem of training for technical positions in industry professional associations cannot be said to have given anything like adequate attention to the many important questions involved The great demand in mechanized industry for highly trained workers possessing a wide range of technical knowledge cannot be met without their co-operation Apart altogether from its reaction on the position and efficiency of the scientific worker in industry the solution of this problem has social aspects at least as important as its effect on industrial efficiency The provision of such highly trained workers would do something to counteract the ill effects of the monotony of mechanization which have sprung up with the passing of the craftsmen and would also make for the mobility of labour and lessen the tendency of specialized work to create men who are unemployable in other capacities

Here and elsewhere as in its references to the work on nutrition the extension of the principle of social insurance the continued tendency towards shorter hours of work the report marks signs of progress and opportunities for further advance by international co-operation The main value of the report lies however in the world picture it gives and the clear warning it sounds as to the danger of certain policies which are widely countenanced to-day No thoughtful reader can fail to recognize the necessity for facing a changed situation and evolving new methods to deal with it The very expansion of the activities of the International Labour Organization itself to meet the increased need for international co-ordination with the passing of economic *laissez faire* the increased importance attached to the problems of agriculture migration housing nutrition indigenous labour attest the existence of an immense amount of international co-operation even in these days of anxiety and unrest and forecast the immense opportunities of development in many of which scientific workers have their part to play

Beyond this the distribution of economic power is shifting The economic development of the Far East is inevitable and there is little doubt that Europe will ultimately lose some of its pre-eminence in the economic sphere a process likely to be accentuated by the division of Europe into groups pursuing different social objectives and working upon different economic principles Here again are problems to be worked out rather than fought out and Mr Butler's survey is pregnant with challenge to commercial and industrial statesmanship

Ultimately however it is the challenge to men of good will everywhere to unite in the task of securing for all mankind the advantages which the achievements of modern technology have put within our grasp that most commends the report The prostitution of scientific knowledge to destructive purposes and the pursuit of retrograde national economic policies threaten the whole social edifice and with it the freedom and continuity of scientific work itself For scientific workers Mr Butler poses clearly the question whether they are prepared to take up the arduous task with their fellow citizens of evolving means of arresting the drift to disaster making their own special contributions to the solution of specified technical problems or by their indifference and neglect allowing the forces of disruption and retrocession to gain strength until scientific workers are overwhelmed with the rest

British and German University Enrolments

IN another column (p 175) we print an article on Numerical Changes in the German Student Body by Dr E Y Hartshorne of Harvard author of German Universities and National Socialism The main conclusions in Dr Hartshorne s article may be summarized by saying that the reduction in number of students in German universities and seats of higher learning was approximately 42 per cent between 1932 and 1937 so that where there were a hundred in 1932 there were only fifty eight in 1937 The process has since continued and it seems probable that there are now not more than half the number of students in Germany that there were in 1932 Of the survivors more than a third—approximately 34 per cent in 1937—were students of medicine The great reductions have been in humanities in pure science and in law and allied studies These conclusions naturally suggest an inquiry whether there are similar tendencies if of a less degree in the British student body A preliminary investigation of the returns of the Universities Grants Committee shows that this question must be answered in the negative

Since the academic year 1933 34 there has been a slight fall in the number of students entering British universities The changes are of the order which those who administer universities regard as normally associated with fluctuations of prosperity There is no reason to suppose that they have any permanent or deeply seated social causation Moreover within the British student body itself there are only minor fluctuations in the distribution of numbers The British classifications are scarcely comparable to the German but with due reservations it is possible to construct tentatively a comparative table of student groups in Great Britain and Germany expressed as percentages of the total enrolment in each country Such a table can be interpreted however only in the light of the enormous absolute fall in the total number of German students

It will be seen that the highly significant drop, both relative and absolute in the sciences and in engineering in the greatly diminished German student body has no parallel in the British universities A distant analogy may be suggested in the rise in the percentage in medical studies in the two countries The relatively greater attention paid to these by British students is however easily explicable by the rise in importance of the social services in Britain and the increased demand for British trained medical men overseas

PERCENTAGES OF TOTAL ENROLMENT

	1932 33	1936 37
Agriculture Great Britain	1 6	9
Agriculture Germany	1	
Pure Science Great Britain	16	10 3
Natural Science and Mathematics Germany	11 1	7 0
Technology Great Britain	9 0	9
Engineering Germany	12 5	11 4
Medicine Great Britain	4	6 7
Medical Sciences Germany	7 9	33 9

So far as foreign students are concerned the movement in Great Britain is in the opposite direction to that in Germany The report of the Universities Grants Committee notes that the number of students from overseas in British universities reached in 1936 37 the record figure of 6 792 This is an increase of about 50 per cent over 1932 33 Dr Hartshorne records a decrease in the number of foreign students in Germany from 6 693 in 1932 33 to 4 768 in 1936–37 The Universities Year Book of the British Empire shows the countries of origin of students from abroad in British universities The numbers from Germany in the six years 1932–33 to 1936 37 were respectively 169 375 436 439 416 444 These may be compared with the corresponding numbers of students from Holland 46 55 42 55 69 58 and from France 80 73 81 78 76 50 We leave our readers themselves to judge whether the increase in the number of students from Germany since 1933 is due to an increased recognition of the advantages of study in Great Britain or to the racial and other limitations which are now imposed in that country upon entrance to universities

Biological Aspects of Health

Biologists in Search of Material
An Interim Report of the Work of the Pioneer Health Centre Peckham Pp 104 (London Faber and Faber 1938) 2s net

A SMALL company of private individuals established what they described as a Pioneer Health Centre in April 1926 in a small house in Peckham London It was situated in the middle of a densely populated artisan district and staffed with a resident medical officer a social secretary and a housekeeper Families living in the neighbourhood were invited to join a family club for a small weekly sum in return for which they were offered a periodic medical and dental overhaul for each individual a parents clinic with men and women doctors ante natal post natal and infant welfare clinics and to these were added an orthopædic clinic and a children s afternoon nursery The service offered to each family was advisory No disease received treatment at the centre Its objects were inquiry social and medical investigation to evoke a desire for health to detect and direct attention to the beginnings of disease and to give advice as to how to procure necessary and effective treatment After several years experience an explanatory book was issued entitled The Case for Action (1931) and now a report is published under a rather formidable and ambiguous appellation of the principal findings

The document now issued explains the growth and expansion of this interesting and somewhat unusual family club in and around which various social activities have grown up The report is concerned with the incidentals of the readjustment and rehabilitation of the sick and the promotion of health But it necessarily raises many large social and medical questions some of which are controversial and others open up issues which are not perhaps as fully considered or presented as the reader would like The Case for Action was widely criticized locally at the time because it seemed to be insufficiently realistic of the actual public services provided for the control and treatment of disease and for the promotion of public health in Peckham and elsewhere The Case seemed to be more one for amendment of private practice and the existing medical services than the establishment of yet another form of clinic and one not easily assimilable with existing institutions Perhaps the conservative mind of the British public did not apprehend the purpose of a social club for families to have periodic medical examination without a bottle of medicine perhaps the purpose itself was presented in terms too technical and philosophical to be attractive to the lay mind However this may be the scheme has reached a stage when it is evident that it has confirmed some of the findings of Sir James Mackenzie s work in Burnley and at St Andrews and not a few of the findings of the institutions in America which advocate and practice the periodical medical examination of the normal person There is much to be said for this as the Metropolitan Life Insurance Co of New York long ago proved as Mackenzie proved the value of early subjective symptoms Whether our urban populations are better satisfied when the medical man is biologist and themselves are material is another question There is certainly no one more popular with them than the family doctor and none more keen on health when they understand it We must remember that Hippocrates himself said if you miss being understood by laymen you will miss reality

One thing is equally plain The Peckham Health Centre has excellently demonstrated beyond all doubt or question the great principle old and ever new of the importance of seeing and knowing the *family* both in diagnosing disease and in teaching the individual the way to health and still more in detecting disease which is minor or unsuspected This was one of the advantages of the old fashioned family physician But this is not the only advantage revealed by the Centre There is also the gain of a regular overhaul (so much advocated in America and so little practised in England) It would also be well that such examinations of the normal should have the purpose of health education rather than the objective of detecting unforeseen disease One of the strong points indeed the primary purpose of the Centre is the promotion of personal hygiene its assessment and indications and the increase in length of life in capacity and in well being and happiness which may result from it

We are glad that the promoters in this second statement are more positive and constructive than in The Case for Action —and naturally so as the result of their labours—and are consciously or unconsciously wisely adjusting their case to the current advances in national health and the progress which has occurred in the locality since 1926 The sections dealing with the methods of examination and with nutrition are excellent and full of suggestion to many other clinics Indeed their experience in regard to nutrition is timely and very instructive The Centre families have no shortage of food and are in contact with good and cheap markets and able to obtain sufficient and suitable food, *and yet there is malnutrition*, some of it severe. In short, the problem of nutrition cannot be solved by confining ourselves to food, quantity or quality. Apparently iron and calcium deficiency, the presence of worms, various febrile states, and ineffective assimilation of the food are responsible for much of the poor nutrition. Thus it seems there is no panacea for malnutrition, not even family allowances. Its cause, or one of its causes, is ineffective utilization by the body of the food consumed. This section of the report is very illuminating.

It seems that the Centre is not recruiting or keeping its membership quite as much as it had anticipated, and is not receiving all the support it had fairly hoped for, with the result that it is unduly restricted in the fulfilment of its purpose. This, we fear, is the usual disability of all pioneers. But the promoters of the scheme need not despair; their report contains positive elements of utility, and they have accomplished much in health education.

Hamilton and Geometrical Optics

(1) Geometrical Optics:

an Introduction to Hamilton's Method. By Prof. J. L. Synge. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 37.) Pp. ix + 110. (Cambridge: At the University Press, 1937.) 6s. 6d. net.

(2) Geometrische Optik.

Von C. Carathéodory. (Ergebnisse der Mathematik und ihrer Grenzbegiete, Band 4, Heft 5.) Pp. iv + 104. (Berlin: Julius Springer, 1937.) 9.90 gold marks.

(1) FEW men were more versatile than Sir William Rowan Hamilton (1805-1865). In early youth he showed amazing linguistic ability, and attained a high standard in Latin, Greek, Hebrew, Italian, French, Persian, Arabic, Chaldee, Syriac, Sanskrit, Hindustani, Bengali, and other languages. He then turned to mathematics, astronomy and physics, and at the age of seventeen years he began to produce original work in geometrical optics. Hamilton's achievements were so great and so varied that it has taken the scientific world a long time to appreciate their full extent. Nineteenth century mathematicians esteemed him principally for his theory of quaternions. Since the rise of quantum mechanics, we now realize the fundamental importance of Hamiltonian dynamics. His optics, although his earliest work, has been the last to be appreciated.

The long neglect of Hamilton's methods in geometrical optics may be attributed to the fact that he attached primary importance to their theoretical aspect, and so he allowed his extensive work on the practical applications to the design of optical instruments to remain unpublished. These manuscripts were almost unknown until 1931, when they were printed in volume 1 of his "Collected Papers" (edited by A. W. Conway and J. L. Synge). Another reason why practical designers have neglected Hamilton's work is that, as published, it dealt throughout with the highly general and difficult case of anisotropic media, although it had been originally worked out for the much simpler isotropic case, which is all that is usually needed.

Hamilton's method is based on Fermat's principle, originally stated in the metaphysical form, "Nature always takes the shortest path." More accurately, the path by which light travels from one point A' to another A will be such that the time taken will be, in most cases, the least possible (and in general what is called 'stationary'). Hamilton's *characteristic function* V is proportional to this time, and theoretically all his results are obtainable from the mathematical conditions that V should be stationary. In practice, however, it is difficult to calculate V for an optical instrument. It is easier to deal with the *angle-characteristic* T, proportional to the time from N' to N, where N' is the foot of the perpendicular from a fixed point O' on to the initial ray, and N is similarly derived from the final ray and another fixed point O. We can also use the *mixed characteristic* W, proportional to the time from A' to N. H. Bruns (1848–1919), who, unacquainted with Hamilton's work, rediscovered part of it, though in a more complicated form, introduced the term *eikonal*. One of his eikonals was equivalent to Hamilton's T. Others were obtained by drawing planes through O' and O perpendicular to the axis of the instrument, cutting the initial and final rays in P' and P respectively, and then considering the time from N' to P, or from P' to N. These eikonals are functions of four variables, whereas V involved six, W five, and only T as few as four. Prof. Carathéodory considers that Bruns made an important advance on Hamilton's work in this respect, but Prof. Synge strongly dissents from this opinion, and declares that the use of the word eikonal is neither necessary nor desirable. His tract is a simple and straightforward account of

V W T with their applications to the leading properties of optical instruments He deals with the relation between object and image the foci focal lines and planes nodal points principal points magnification the defects (spherical aberration astigmatism coma curvature of image and distortion) Abbe s sine condition and some cases of dispersion (chromatic aberrations) For the system treated as a whole Hamilton s methods (or their modifications) seem the most powerful yet devised though for isolated problems shorter solutions can be found

(2) Instead of starting from Fermat s principle geometrical optics may be based on Huygens s principle that the wave front is the envelope of secondary waves the centres of which are on a previous wave front The rays (in an isotropic medium) are the normals to these wave fronts Prof Carathéodory reversing Hamilton s procedure starts with Huygens s principle which he develops by the aid of Cauchy s theory of characteristics of differential equations This leads to Poincaré s and Cartan s theorems on integral invariants which are generalizations of Malus s theorem that rays initially normal to some surface finally emerge after any number of reflexions and refractions as normals to another surface Much stress is laid upon *canonical direction co ordinates* which are analogous to the momentum co ordinates used in Hamilton s dynamics The usual equations of the calculus of variations expressing the conditions for a stationary path are replaced by the canonical equations of the Hamiltonian function again as in dynamics In the subsequent work a great part is played by Lagrange s brackets and canonical transformations Rather unexpectedly these lead to the eikonals and we suddenly realize that the formidable pure mathematics has after all a physical application However Prof Carathéodory s emphasis is certainly on the mathematics while Prof Synge s is on the physics Both books may be warmly commended and the fact that Hamilton s work can be developed in two such different ways is evidence of the versatility of his genius

Presentation of Physical Chemistry

(1) An Introduction to Physical Chemistry

By F A Philbrick Pp ix + 368 (London J M Dent and Sons Ltd 1937) 5*s*

(2) Elementary Physical Chemistry

By Prof Hugh S Taylor and Prof H Austin Taylor Second edition Pp xiv + 664 (London Macmillan and Co Ltd 1937) 16*s* net

(3) Lehrbuch der physikalischen Chemie in elementarer Darstellung

Von Prof Dr John Eggert Vierte verbesserte Auflage Pp xii + 681 (Leipzig S Hirzel 1937) 25 50 gold marks

(4) Praktische Einführung in die physikalische Chemie

Von Karl Lothar Wolf und Hans Georg Trieschmann Erster Teil Molekule und Krafte Pp viii + 114 (Braunschweig Friedr Vieweg und Sohn 1937) 4 80 gold marks

(1) IN recent years physical chemistry has been specifically included in the syllabuses for the various higher school certificate examinations and this book is intended for students who are working for these and similar examinations All the topics generally included in elementary physical chemistry are discussed and in addition there is a useful chapter on the theory of analysis The treatment is simple and clear and essentially descriptive rather than mathematical The point of view is commendably modern the student whose knowledge of physical chemistry is based on this book will find that he has little to unlearn during the course of his more advanced studies at the university Subjects such as radioactivity isotopes atomic structure and electronic theory of valency are not included and the author has wisely avoided a number of other matters which are much better left to a later stage

The reviewer s chief criticism of the book as a whole is that the historical background has been almost entirely ignored Traube and Pfeffer are not mentioned in connexion with osmotic pressure where the only names recorded are those of Morse and Frazer and Graham finds no place in the chapter on colloids where due credit is given to von Weimarn and to Bredig There are however many good points about this book it would be impossible to refer to them all but special mention must be made of the neat deduction from the kinetic theory of the pressure of an ideal gas

When another edition is in preparation the author would perhaps consider making some small changes for example it is doubtful whether sulphuric is weaker than hydrochloric acid (p 103) and whether simultaneous adsorption of both reactants is generally involved in heterogeneous catalysis (p 120) The molecular conductivity has fallen into disuse for good reasons and should be replaced by equivalent conductivity A phase diagram for phosphorus would help considerably in connexion with the description on p 302, and mention of the terms enantiotropy and monotropy would not be out of place there These matters are, however, relatively unimportant, for the book is one which can be recommended for its intended purpose, both pupils and teachers should benefit from its use

(2) The first edition of Taylor's well-known "Elementary Physical Chemistry" suffered to some extent from the fact that it had been adapted from the two-volume treatise compiled by a number of different authors there were certain gaps and some inequalities of treatment The appearance of a new edition, revised by Profs H S and H A Taylor, is to be welcomed, because there has now been an opportunity for the material to be welded into a more coherent whole

In addition to a general revision, two new chapters have been introduced, one deals with the development of the quantum concept and its application to atomic and molecular systems, whereas the other considers these applications in more detail with reference to gases, and includes such subjects as rotational and vibrational heat capacities, ortho- and para-hydrogen, and zero-point energies Elementary quantum concepts have also been introduced into the chapter on the velocity and mechanism of chemical reactions, and this portion of the book, as is to be expected from its authors, is of exceptionally high standard

The section on the atomic concept of matter has been brought up to date, but it is unfortunate that the impression is given (p 36) that the nucleus is still considered to consist of protons and electrons In accordance with modern ideas the treatment of solutions is based on Raoult's law, the authors should, however, have given greater emphasis to this point in the discussion of ideal solutions (p 327). Although the chapters on electrochemistry are quite good, the treatment of salt hydrolysis is open to criticism, and it is hoped that an early opportunity will present itself for this section to be amended

The book concludes with three appendixes, dealing respectively with the deduction of Maxwell's distribution law, of Planck's expression for the mean energy of a linear oscillator, and of the imiting law of Debye and Hückel The first and ast of these involve fair mathematical skill, and t has evidently been considered advisable to keep them out of the main body of the text this procedure will meet with the approval of many students who are still finding their way among the foothills of that imposing mountain range which is physical chemistry

Since the first edition of this book was published n 1927 it has been reprinted four times, and there s every reason to expect, from its content and style, that the demand for the new edition will be even greater

(3) Although the third book on the list is described as an "elementary presentation", it is doubtful whether it could be appreciated by a reader who has not already some knowledge of the fundamentals of physical chemistry, and this point should be borne in mind The treatment of atomic structure, and of related topics, is particularly good, but a severe critic might question the wisdom of devoting more than a quarter of the book to the consideration of atomic and molecular structure, although less than four pages are accorded to the modern theory of valency There is always a danger, when writing a relatively advanced text-book, of occupying too much space with matters in which the writers are specially interested or which happen to be topical, with the result that others of fundamental importance are treated too briefly This may be illustrated by the fact that in this book only 16 pages are given to the osmotic properties of dilute solutions, including experimental methods and diffusion in the opinion of the reviewer, this is too small a proportion of a book with 640 pages of text

The arrangement of the material is unusual in some respects, although it could probably be readily justified It is surprising, however, to find that the phase rule is not mentioned until after the treatment of one- and two-component systems Nevertheless, this is one of the most interesting of modern text-books of physical chemistry Its wide appeal is shown by the translation of earlier editions into English, Italian, Russian and Spanish, and four German editions have been published in eleven years

The present issue, like its immediate predecessor, has been revised by the author in conjunction with Dr Lothar Hock, and it is quite evident that the work has been well done not only have many portions been rewritten or rearranged, but also the material added has necessitated an increase of nearly 80 pages The book has one disadvantage from the point of view of readers in Great Britain and in the United States the thermodynamic symbols are not those generally employed in these countries

(4) The book by Wolf and Trieschmann is of an unusual type it is not so much a text-book of practical physical chemistry as an account of the principles of the subject A number of exercises are suggested and their theoretical basis explained, but for experimental details the reader is referred to standard German texts of theoretical and practical physical chemistry and physics Where these are available this small book, which covers the field of ions, atoms and molecules, and gases and liquids, should be very useful, but otherwise its value is restricted. S G.

Physiological Chemistry of the Bile

By Harry Sobotka Pp xii + 202 (London Baillière, Tindall and Cox, 1937) 13s 6d

THIS volume aims at providing the experimental worker in physiology, pharmacology and experimental medicine with a survey of our present knowledge of the biliary secretion It is intended to be read however, in conjunction with a companion volume by the author called Chemistry of the Sterids" Without reference to the latter, certain sections on the bile acids in the present book are not clear, since the author refers to the rings and carbon atoms of the bile acid structure by numbers, for example, 'ring III', $C_{11}-C_{12}$', these sections would be much easier to read if a skeleton structural formula of the bile acids with the rings and C atoms appropriately numbered were included, thus avoiding unnecessary references to the companion volume

The first half of the book deals mainly and thoroughly with the composition of normal bile, and there is an introductory chapter on the general physiology and structural relations of the tissues involved in bile formation One feels that a book on the physiological chemistry of the bile is incomplete without at least a brief account of the bile pigments, a discussion of which has been excluded from the present volume The author however, disarms criticism by stating that they could not be treated adequately without an extensive exposition of the physiology of the blood pigments and the chemistry of pyrrole derivatives

The last half of the book deals mainly with the pharmacological aspect, especially with choleretics and cholagogues A brief account is also given of bile and bile acids in pathological conditions

The book should be stimulating to research workers, since gaps and uncertainties in our knowledge of the bile, together with suggested lines of investigation, are clearly indicated and constantly referred to by the author Many of the earlier results in this field require re investigation There is an extensive bibliography, which occupies one quarter of the book The latter has the merit of satisfying a need and of collecting together in an orderly fashion a large number of scattered data concerning the biliary secretion R T W

On Guard against Gas

an Account of the Principles of Gas Warfare and of the Steps to be taken by the ordinary Citizen to defend his Family By H A Sisson Pp 91 (London Hutchinson and Co (Publishers), Ltd, n d) 2s net

IT is a pleasure to turn to a book dealing with poison gas which has been written by an expert who has had personal experience of it not only in the laboratory and experimental ground, but also on the battlefield itself Major Sisson held an important appointment in the Gas Directorate of the British Expeditionary Force during the Great War, and he has first hand knowledge of the practical use of gas and can estimate its probable effects if it is employed against a civil population His opinions, therefore, should carry weight with the majority of people, who are naturally ill informed in a matter remote from their ordinary experience and have been grossly misled in the past by sensational writers

The author considers that gas would be a minor danger in an air raid if people can be made to understand it Besides being told what precautions to take against it, they ought to learn the reasons for the recommendations made It may not be possible to make one s home safe against fire and explosives but it can certainly be made reasonably proof against gas, and scarcely any serious casualties need be expected from it among a fully instructed community

The book is not intended to be a substitute for the official A R P Handbooks, which the author considers excellent, but to supplement them by giving a more general view of the subject in the form of a connected story It describes in non technical language the different kinds of gas that are most likely to be used in air raids and explains their action and the method of catching them in modern respirators There are also chapters on the experience gained from the Great War in regard to the employment and effects of gas, and on the preparation of gas shelters in the home

This excellent little book is within the reach of every pocket and it should be widely read especially by nervous householders C H FOULKES

Bio-Politics

an Essay in the Physiology, Pathology and Politics of the Social and Somatic Organism By Morley Roberts Pp xv + 240 (London J M Dent and Sons, Ltd 1938) 15s net

MR MORLEY ROBERTS S study of the social organism as he admits and indeed proclaims, is based on analogy, specifically on the thesis that the communities of bees, ants and termites and therefore also human societies, resemble organisms 'Whatever the groups, the laws of organic development which produce order, form, interdependence and differentiation are everywhere the same Hence studies in the pathology of single animals can be applied to the functions of social and national groups 'Where protoplasmic units, however simple or complex, work together in symbiosis or communal life, they can best be considered as organisms, and as such liable to the diseases and disorders which change or destroy them He is not afraid of carrying his analogies to an extreme For example "After what was said earlier on immunity, students of medicine will have no difficulty in thinking that sarcoma, or malignant revolt of various connective tissue elements, may be nearly matched by a revolt of the police '

It would take many pages to explain that Mr Roberts s assumption of the existence of biological laws of any kind is rash, as the "laws" are no more than abstractions from observations limited strictly to the precise conditions in which they were made, and without wider validity But he is a writer of great ability, and has collected a large number of interesting facts, so that his book is stimulating and useful

Geology and Archæology of the Hadhramaut, South-west Arabia

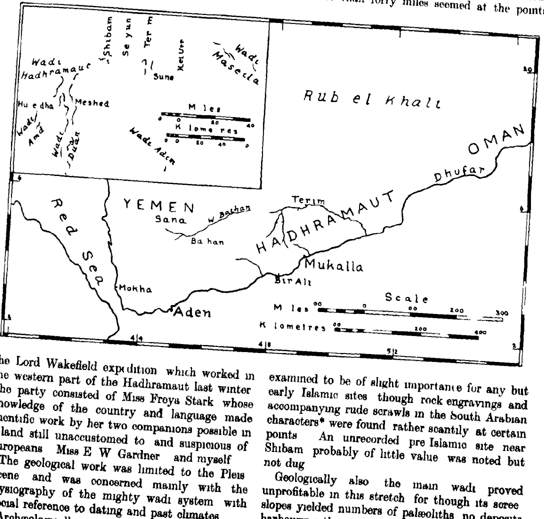
Preliminary Notes on the Lord Wakefield Expedition

By Miss G Caton-Thompson

ON September 18 1937 Dr S A Huzayyin gave a preliminary account in NATURE of the results of the Egyptian University Scientific Expedition to the Yemen and Hadhramaut It may be advantageous therefore also to record in brief the geological and archæological results of the Lord Wakefield expedition which worked in the western part of the Hadhramaut last winter The party consisted of Miss Freya Stark whose knowledge of the country and language made scientific work by her two companions possible in a land still unaccustomed to and suspicious of Europeans Miss E W Gardner and myself

The geological work was limited to the Pleistocene and was concerned mainly with the physiography of the mighty wadi system with special reference to dating and past climates

Archæologically we were confronted by a land of romantic traditions centring round the incense trade of which the early material culture was virtually unknown and which consequently had tended to become a dump of untested theory not unusual in regions where literary and epigraphical records have been unpartnered by archæological facts Consequently all relics of pre Islamic habitation irrespective of date were welcomed provided only these were found in association and *in situ*



The Wadi Hadhramaut from Terim westwards for more than forty miles seemed at the points examined to be of slight importance for any but early Islamic sites though rock engravings and accompanying rude scrawls in the South Arabian characters* were found rather scantily at certain points An unrecorded pre Islamic site near Shibam probably of little value was noted but not dug

Geologically also the main wadi proved unprofitable in this stretch for though its scree slopes yielded numbers of palæoliths no deposits harbouring them *in situ* were found If gravel terraces exist they are deeply blanketed by great deposits of æolian silt which floor the valley and drown the lower talus slopes

In the Wadi Amd a northward draining major tributary of the Wadi Hadhramaut where shortly before Christmas we settled in the little town of Hureidha luck changed and we were kept busy with a superabundance of material and its systematic excavation

---

* It seems better to avoid the terms Himyaritic and Sabæan or their compound until they are chronologically and geographically defined by archæological method

GEOLOGY*

The Wadi Amd is two to three kilometres broad and is floored like the main valley with a gently sloping fine æolian silt a deposit partly wind partly water laid Bordering the main flood channel gravel is exposed both in terraces and interbedded with the silt These we were anxious to date for after the original cutting of the valley to some unknown depth the deposition of gravel and silt were the most important events in its history There are three terraces The highest and best developed lies at ten metres above the wadi floor the lower ones are laid against it at five and three metres

The ten metre terrace is distinguished from the others by the æolian silt interbedded in it and in places overlying it This is identical with the silt of the valley floor and the finding of tools both in it and more abundantly in the gravels dates the infilling or at least the upper part of it to palæolithic times The implements specially numerous in the ten metre terrace belong to the Levalloisian culture but unlike many of their relatives in Egypt in Palestine or others as geographically near as Somaliland these Hadhramaut tools are crude in workmanship and undifferentiated in type Here no succession of stone age cultures breaks the monotonous continuity of the Levalloisian tool making Hand axe cultures seem to be absent (the Egyptian expedition found one specimen in the Yemen) likewise the blade and burin industries of which the route into Africa may therefore not be sought via Southern Arabia as many including myself had believed Wherever we searched on the high plateau or jol on the spurs and screes of the Wadi Hadhramaut in the lateral valleys the Levalloisian type of tool alone was found and in great numbers It seems as though its manufacture must have persisted in these parts long after Africa and the Near East had progressed to more advanced stages of stone age development An obsidian industry of small blade cores and geometric forms was indeed found but this was proved conclusively to be historic and at most not older than a few centuries before the Christian era—a conclusion already reached by Dr Huzayyin

The Egyptian expedition had traced in the Yemen a series of pluvials in prehistoric times and a minor oscillation in the historic period the latter based on archæological evidence such as dry wells and empty tanks We cannot say we found indications of greater rainfall in the Hadhramaut in historic times but on the evidence of the palæolithic gravels it seems indisputable for part of the Pleistocene

That the æolian silt deposition in the valleys is due to climatic rather than to local physiographic causes such as ponding by lava flows in the lower reaches of the main wadi seems assured also by our observation of similar deposits choking the shallow valleys on the high plateau far removed from the influence of Wadi Hadhramaut and lying between it and the sea Climatic implications were extended further by the discovery of Pleistocene travertines crowded with vegetation these which were dated by derived pebbles in the ten metre gravels may throw interesting light on the past flora of the country

If the upper part of the filling of these great wadis trenched 300 metres in the limestone plateau is Middle to Late Pleistocene it is evident that the original cutting is pre Quaternary The climatic changes of the European Ice Age with which the cutting of the Hadhramaut valleys had formerly been correlated affected only the nature and amount of their subsequent infilling and re cutting

ARCHÆOLOGY

The work which was necessarily of an exploratory nature was centred on Hureidha It covered the chief aspects of pre Islamic activities in the region and yielded information concerning domestic dwellings irrigation works and places of worship and burial

No reliable information could be had beforehand as to prospects of getting labour for digging and difficulties had been prophesied It was a surprise therefore to find a sufficiency of recruits for the unfamiliar work They were on the whole intelligent and agreeable to direct and compared well with similar untrained labourers in the Near East

Irrigation and Houses At first glance the ruin field intermittently scattered over about ten square kilometres of the loess like plain looked uninviting Its noticeable feature was a large number of fairly evenly spaced stone rubble heaps which sprang from bare wind swept ground Detailed mapping proved them to be relics of a big irrigation system In this respect fortune had economized her resources for it so happened that Miss Gardner some years ago had mapped a Ptolemaic irrigation system discovered in the desert Faiyum Comparison of the two systems will be an interesting study in ancient man s ingenious inventions in both regions to turn a desert into a fertile plain on a scale seldom initiated to day

---

* I am indebted to Miss Gardner for the geological notes

The source of the water was the monsoon summer rain the flood was led off the main channel far above the irrigated area and carried to it by a canal 16–20 metres broad still discernible in the sandy waste From this numerous smaller channels distributed the water in a network of runnels

There was no evidence that a town or even a village had existed amongst these fields now desert But some knolls smothered in sand showed by a scatter of sherds that house foundations singly or in clusters lay beneath One such homestead was excavated and disclosed a five to six roomed mud brick building formerly limewashed fitted with mud brick benches Logs of wood reinforced the door treads and the ceiling had been constructed in the fashion still practised in the region of twigs laid in parallel bundles across rafters and over daubed with mud Few objects except broken pots were found here but the form of these supported by inscribed fragments served to equate the dwelling with the temple and tombs we excavated near by

The Temple The temple the first of its kind to be excavated in South Arabia which was completely buried in drift stands in the formerly cultivated plain It is an oblong structure 17 metres × 20 metres in size set on a raised platform capping a natural eminence with its main façade on the south west From here the ground falls sharply to a depression or basin the artificial origin of which is attested by a bordering throw up of clayey silt now greatly weathered but still impressive in extent We noted a similar depression at the foot of the unexcavated temple mounds at Meshed and surmise that these basins may form an integral part of temple plans in South Arabia

The podium is faced by massive stone rubble walls four to five metres high and half a metre thick set on a batter of 7° Twenty one courses of roughly shaped sandstone blocks bonded and mortar bedded still stand topped by a coping of huge ashlar blocks of rusticated work with drafted borders The interior was levelled up by a dry filling of great boulders A top dressing of small mortar laid pebbles formed the bed of a flagged pavement which still lay intact over a considerable area

Little remained of the superstructure except the stumps of five tapering blocks with square bases set in parallel alignment which may be the remains of thin columns* or aniconic objects and vestigial partition walls of polished lime plaster of finest quality, in part recessed These define a forecourt giving access to the main pillar area through a narrow flagged passage and entrance

Structural evidence was obtained for at least three phases of building rebuilding or readaptation which finally raised the platform floor above that of the podium coping and extended the original building by important additions to the south west front These are referred to in one of more than fifty inscriptions found and interesting light may be thrown on rebuilding activities and their authors names when all have been studied by Prof Ryckmans of Louvain who has most kindly undertaken the task

The temple platform was reached by two stone stairways One the older and more important though even so not part of the original structure gave access from the south east its base widened out to nearly three metres and an inscribed slab had been carelessly reutilized in a tread The other later stairway only a metre wide approached via the south west angle Built into it also were several discarded inscriptions Both these flights took off from a circumambulatory pavement considerably above the surrounding level of the original building Sherds were collected in test pits down to 2 80 metres below this pavement

There is reason to suppose that the building was originally wholly plastered pavings stairways and partition walls were certainly thus faced Whether the rubble retaining walls were treated in the same way is uncertain but not improbable

Clearance of the very interesting peripheral buildings crowded round the temple base had of necessity imposed by time to be confined to those lying at the foot of the south west façade itself added in the latest period A temenos area was therefore not delimited The cluster of outlying buildings was however of outstanding interest for it included a pair of perfect and remains of other imperfect apsidal structures of small size characterized by a central free standing altar like stone surrounded by a low kerb or by a bench of flat slabs rectangular on three sides convex on the front

That these places though amongst the latest additions were shrines of aniconic religion seemed proved for standing erect against the base of one such altar were two baetylic stones one rudely fashioned from a stone brick into human form the other a symmetrically tapered rough dressed stone Both were carefully embedded upright in plaster and before both were placed stone incense burners of rectangular form stained red and patterned as well as earthenware saucers and a stone offering tray

The temple referred to in one of the dedicatory inscriptions by the name of Madabûm, was devoted to the worship of the Moon God whose name occurs on all the inscriptions so far examined by Prof Ryckmans, and whose symbols appear also on funerary pottery and stone. To that deity burnt offerings were made in fire-altars

---

* Columns are an important feature in pre Islamic temples in Yemen (*cf* Rathjens and Wissmann Südarabien Reisen Band 2 Hamburg 1932)

The inscriptions must belong to the earlier periods of the building's existence, for the large number actually *in situ* were obviously in secondary, and not original, positions Some indeed had been built-in upside down or sideways to the lettering, others were exposed only on removal of a plaster-coated floor or step, yet others lay beneath the circumambulatory pavement, or had been ruthlessly cut down to fit their new position Traces of a red staining like that on the incense-burners were repeatedly observed upon them

Of considerable interest in this context is a graffito of a running camel with outstretched neck, resembling in style many of the naturalistic rock-drawings sometimes rashly assumed to be of prehistoric age

The Tombs Those examined lay in the lower slopes of the cliffs some half-mile from the temple and dwellings, the general contemporaneity of which was proclaimed by the pottery common to all They consisted of artificial caves quarried back into the sloping talus, and were roughly circular cavities of varied size, the couple excavated measured 8 metres in diameter by 2 40 metres in height Drift and cave-rubble filled them almost to their ceilings One example had low benches cut in the walls to receive the corpses singly, or in double-decked loculi This tomb was entered by a narrow down-sloping dromos 5 metres long, cut into the cliff side, passage and entrance had been skilfully repacked with scree, difficult to distinguish from the natural undisturbed article The cliffs here seem to be riddled with cave tombs, a few of which have been cleared by bedouin and reused as dwellings or goat pens Others have been partially plundered and abandoned

The second cave-sepulchre examined amplified and corrected the deductions drawn from the first It contained one bench only, upon which a skull and single bone rested amongst a group of ten pots, shells and miscellanea. But here, unlike the other tomb, the floor itself presented an astonishing mass of sherds and pottery vessels—sixty more or less complete ones were recovered, some inscribed—mixed up with forty-two skulls, disarticulated and fragmentary bones, and simple grave goods It seemed at first legitimate to infer very complete plunder of a communal tomb by contemporary robbers But this in no way explained the singular disproportion gradually observed in the parts of the skeletons present For example, whereas this chamber contained forty-two skulls, it yielded only seven lower jaws, and these mostly in fragments A theory of fractional burial seemed beside the mark, for the confusion exceeded the bounds probable in any pious practice It seems preferable to invoke the explanation of an ossuary In the first place the population, as evidenced by the loculi caves visited, buried their dead in family sepulchres Over a fairly prolonged period (during which the temple was twice altered) an insufficiency of suitable tomb-sites within reasonable distance or permitted limits developed The older tombs were cleared of their mouldering bones and grave goods, and these were unceremoniously redeposited *en masse* in an ossuary Future work will test the validity of this interpretation, which on present data seems best to fit the facts

Twelve skulls alone were complete enough for preservation They are markedly long-headed, and uniform in type, but along with the other finds await detailed study

Viewed as a whole, the semi-civilized culture thus brought to light near Hureidha can lay no claim to be in the vanguard of progress of its period Pronouncement on the date must be reserved, it probably lies within the last few centuries before the Christian era Apart from the irrigation system, imitation is more apparent than initiative. The pottery is monochrome, hand-made and clumsy, though fairly ambitious in form Debased amulets of Egyptian derivation were cherished, and seals denote intercourse with Syrian or Babylonian regions The beads, on the other hand, contain Eastern as well as East Mediterranean elements, and should, when expertly examined, yield their quota of evidence to an interesting story

An exhibition of the finds will be held at the Fitzwilliam Museum, Cambridge, by the courtesy of the director, Mr Louis Clarke, during the meeting of the British Association in August, and will form the first authenticated group of archæological material from the Hadhramaut obtained in excavation

The expedition was primarily made possible by the generosity of Lord Wakefield, to whom archæologists must be under a debt of gratitude for the acquisition of entirely new data, and it received also invaluable support from the Royal Geographical Society, from Mr. Louis Clarke on behalf of his Museum, and from the Ashmolean Museum, Oxford Our thanks, moreover, would be incomplete without acknowledgments to the International Federation of University Women, from which Miss Gardner holds a senior science fellowship enabling her to join the expedition; and finally to Mr. Ingrams, First Political Officer to the Hadhramaut, and to Mrs Ingrams for their cordiality and kindness.

Modern Views in Physics

International Conference

THE International Institute of Intellectual Co-operation is an organ of the League of Nations which at intervals arranges small conferences of experts in various subjects. In the past it has given its main attention to educational, historical and archæological subjects, but recently it has extended into science; for example, not long ago it organized a small conference in Paris on phytohormones, another at Neuchâtel, on the molecular and atomic weights of gases, a third one in Prague, dealing with the publication of ancient scientific manuscripts. It recently embarked on a larger scheme by inviting about thirty physicists to meet in Warsaw for the purpose of discussing the philosophy of physics. The meeting took place on May 29–June 2 under the presidency of Prof. Bialobrzeski; as hosts there were Profs. Rubinowicz, Szczeniowski, Weissenhof, Wertenstein and Wiśniewski, and the following guests accepted invitations: Profs. E. Bauer, Niels Bohr, L. Brillouin, L. de Broglie, C. G. Darwin, Sir Arthur Eddington, R. H. Fowler, G. Gamow, S. Goudsmit, E. Hylleraas, O. Klein, H. A. Kramers, L. de Kronig, P. Langevin, C. Moeller, J. von Neumann, F. Perrin, L. Rosenfeld, E. P. Wigner.

Reports had been prepared in advance by a number of the members to serve as bases for the discussions, and a great deal of profitable argument ensued. The detailed discussions will be printed later by the Institute, and until they appear it is not possible to give more than a very rough impression of the proceedings. The reports were furnished by Bohr on the indeterminacy of quantum mechanics, by L. de Broglie on the relations of quanta and relativity, by Brillouin on the individuality of the elementary particles, by Eddington on the relations of quanta to cosmology, by Milne on his cosmology, by Klein on field theory and by Langevin on the relation of positivism to physics. Heisenberg was also to have made a report on the limits of applicability of our present mechanics in connexion with particles of great energy, but he was unable to attend and his place was taken by Kramers, who has been in close touch with his ideas and, among other interesting things, told us what Heisenberg would have said if he had been there.

It will be seen that the subjects divide roughly into two parts, connected respectively with the foundations of physics and with the recent work on the various kinds of elementary particles. With regard to the foundations, such discussions are of great value in helping to summarize present opinion, but when we consider what that opinion is, it is difficult not to feel rather pessimistic. The enormous triumphs of the quantum theory have all been in the branches and scarcely any in the roots. Difficulties connected with such things as radiation theory and the self-energy of the electron remain much what they have long been, and it is scarcely too much to say that if this conference had been held in 1930 the chief difference would have been that the catalogue of abortive attempts would have been shorter. Indeed the situation was summarized by Kramers in the words: The quantum theory has been very like other victories; you smile for months and then weep for years. The inexpert listener would have concluded from the discussions that the quantum theory is a poor thing and would have wondered why anyone believed in it, forgetting that on such occasions it is the points of difficulty that are considered and that no time is wasted over the very much larger field where there is a consensus of agreement.

It would not be easy to describe what was said about the fundamental difficulties, because from the nature of things the ideas of the speakers are not in clear shape, but there did seem to emerge one real divergence of opinion between what may be roughly called the mathematical minds and the physical. The mathematician tends to attack the problem of foundations by setting down a scheme for the whole universe; it has to accommodate all the necessary characters, relativity, exclusion principle and so on—making use of any technical methods, matrices, wave-functions or double quantization, that suit the author's taste—and he then tries to specialize his scheme so as to deal with the limited problems that the experimenter studies. The opposite view is taken by others, led by Bohr, who insist that nothing can be grasped by the human mind except in classical terms, so that there is always a classical basis—of fields of force, barriers, slits, etc.—underlying every problem of quantum mechanics; the quantal system moves under these controls, and though it may be possible to enlarge the system so as to include more and more particles quantally, it is never possible to go to the limit and include the whole universe. This does seem a real divergence of opinion, and, if the second view is right, the various attempts at world structure of the first type are necessarily doomed to failure.

Some of the most interesting discussions were connected with more technical matters, on which positive results may be attained Thus Brillouin reviewed the present state of our knowledge of the elementary particles , this is nowadays quite a long list as it includes along with the older ones the photon, the neutrino and the heavy electron or 'yukon', as it has been called after Yukawa who first, and before the experimental discovery, studied some of its possibilities The discussion was largely concerned with the relation of spin to the statistics which each particle should obey It appeared that though this is governed by certain rules, so that half spins go with Fermi statistics and whole with Einstein, yet there is a complete lack of proof for the necessity of this connexion Then Eddington gave an account of his theory of electrons and protons, and had to defend his position against criticism from many sides Milne was not there and his report was read but not discussed

The work of the conference was not so heavy but that we had opportunities for seeing the sights of Warsaw, and several brilliant entertainments were given by our Polish hosts, including a luncheon party, where we were entertained by the President of the Republic in the Castle of Warsaw It is noteworthy that in Poland, more than in most countries, a scientific career may lead to high political office, for until the cares of State engrossed his whole attention, the President was himself a physicist, and the Minister of Education, who entertained us at dinner, was, and in his spare time still is, a physical chemist At the end of the conference many of the visitors paid a visit to the beautiful city of Cracow with its historic university Altogether, from both the social and the intellectual side, the meeting was agreed by everyone to have been a great success and the guests carried away most pleasant recollections of their visit

C G DARWIN

Obituary Notices

Mr. W M Mordey

MR W M MORDEY, the eminent consulting engineer, died suddenly at his home in Warlingham, Surrey, on July 1, at the age of eighty two years He was one of the best known electricians, and besides his professional work did valuable research work He was president of the Institution of Electrical Engineers in 1908 and was made an honorary M I E E in 1932

Mordey was born at Donnywell, in the County of Durham, in March 1856 and was the second son of J G Mordey, whose father was an eminent surgeon and had been several times Mayor of Sunderland At the early age of fourteen years he entered the P O Telegraph Service when it had just taken over the telegraphs from the companies A few years later when stationed at Bradford he held classes under the South Kensington regime In 1881 he left the P O service and went to the Brush Company's works at Lambeth He was soon advanced to the responsible position of chief of the test room and became electrical designer in general He did valuable work in developing compound winding for dynamos He gave convincing proofs of the practicability of running alternators in parallel which then became a practical instead of merely a theoretical operation At that time the Mordey alternator was the best parallel running alternator on the market The 'Victoria brush' dynamo designed by Mordey was almost in general use for many years especially for ship lighting He established again t high authority that a good dynamo is also a good motor When working on transformers he studied the magnetic ageing of the iron, and with the assistance of Messrs Sankey succeeded in getting made the material 'stalloy' which was relatively free from many of the ordinary defects Mordey accepted no theory until it had been practically tested and testing meant to him measuring

One of his inventions when he was with the Brush Company was the invention of a dust filled fuse which 'blew' safely on 2,000 volts, alternating current, and was one of the earliest of arc extinguishing fuses

Mordey left the Brush Company in 1895 and set up as a consulting engineer When R A Dawbarn joined him the firm was called Mordey and Dawbarn They carried out some important works in South Africa and South America In his presidential address in 1908 he vindicated the English electrical engineering industry from the criticism that it lagged behind some other countries

Mordey took a leading part in the committee which the Council of the Institution of Electrical Engineers appointed in 1908 to find a suitable building in which to hold its meetings At that time the meetings were held in the lecture hall of the Institution of Civil Engineers which was kindly lent to them The committee decided almost at once to purchase the Medical Examination Hall of the Royal Colleges of Physicians and Surgeons which was then on the market The purchase was effected for £50,000 on a seventy six years lease Since then the membership of the Institution has increased nearly three times, a fact to which Mordey referred with pride a few years ago

Mordey discovered a curious effect produced when certain finely divided minerals were placed in an alternating magnetic field The particles repelled one another and by suitable apparatus he was able to apply the phenomenon to the separation of ores

His earliest published account of these experiments was read at a meeting of the South African Institute of Electrical Engineers at Johannesburg on December 16, 1921 His full statement and his explanation of the effects were given in his Friday evening discourse at the Royal Institution on May 18, 1923

For many years, Mordey was a member of the Council of the Institution of Electrical Engineers and being very sociable he used to stay to many of the Council dinners His criticisms of the papers read were frank, but his remarks were often very helpful He was a member of the Athenæum and of the Alpine Club He loved to talk about mountaineering in Switzerland and climbing the snow-clad hills of Scotland in winter time to the astonishment of resident farmers The profession and the industry have greatly benefited by his work

Mordey was fond of good music and was a member of the Bach choir for many years The early death of his first wife leaving him an only daughter was a great blow His daughter married Major E O Henrici, but after having a family she died comparatively young Another blow to him was the death of his partner Dawbarn He has left many friends who will sadly miss him A R

THE death has recently occurred of Dr Ragnar Rydberg, lecturer in physics in the University of Stockholm at the early age of thirty six years Dr Rydberg's scientific career was mainly devoted to the field of band spectroscopy, from which his beautiful methods of graphical constructions based on extensive spectroscopic data were developed His dissertation Uber Neubildung und Zerfall zweiatomiger Molekule (Stockholm, 1934) also included valuable discussions on problems regarding pre-dissociation phenomena in discharges under different conditions

---

WE regret to announce the following deaths

Dr B T Galloway, pathologist in the Bureau of Plant Industry of the U S Department of Agriculture, on June 13 aged seventy four years

Dr A E H Tutton, F R S, formerly H M Inspector of Schools (Technological Branch), Board of Education and a leading authority on chemical and physical crystallography on July 14 aged seventy three years

News and Views

Prof. M N Saha, F R S.

AFTER nearly fifteen years of service in the University of Allahabad, Prof M N Saha is returning to his Alma Mater, the University of Calcutta, as Palit professor of physics The first occupant of this chair, the gift of a rich Calcutta lawyer to the University, was Sir C V Raman (1918 32), and he was succeeded in 1932 by Prof D M Bose (1932 37) who is now director of the Bose Research Institute founded by his uncle, the late Sir J C Bose Prof Saha graduated from the University of Calcutta in 1915 in applied mathematics, and in 1917 became lecturer in physics in the newly founded University College of Science Between 1917 and 1921, he published a number of papers in the *Philosophical Magazine* and other journals on the application of the special theory of relativity to electrodynamics, on selective radiation pressure and its application to astrophysics, and the theory of thermal ionization of elements The grant of a foreign scholarship by the University of Calcutta enabled him to visit England in 1920–21, and to work in the laboratory of Prof A Fowler at the Imperial College of Science and Technology He was thus enabled to give the finishing touches to his paper "On the Physical Theory of Stellar Spectra" which was published by the Royal Society in 1921, and is now regarded as a work of highest importance in astrophysics When, two years later, the University of Allahabad was just then passing from an examining to a teaching university, Saha accepted the chair of physics there and was called upon to frame the courses of teaching, organize the laboratory, and initiate research work He succeeded in creating a fine school of teaching and research under great handicaps and in infecting his colleagues with enthusiasm, resulting in important contributions to knowledge Students trained by him have already achieved great distinction, among them being Prof D S Kothari (Delhi) and Dr R C Mozumdar in astrophysics, Dr N K Sur in meteorology Dr G R Toshniwal in ionospheric research, and Dr P K Kichlu (Lahore) in spectroscopy

BESIDES research and teaching, Prof Saha has taken a leading part in the organization of scientific life in India In 1931, he was instrumental in founding an Academy of Sciences for the Provinces of Agra and Oudh In his presidential address to the Indian Science Congress in 1934, he advocated the establishment of a National Academy of Sciences for India on the lines of the Royal Society of London This led to the foundation of the National Institute of Sciences (composed of 150 senior scientific workers in India) at Calcutta, of which Sir Lewis Fermor was the first president In 1937, Saha succeeded Sir H Couchmann, the surveyor general, as president of the Institute and was able to obtain a grant for it from the Central Government In 1935 he founded the journal *Science and Culture* with the view of educating his countrymen about the relations of science to national life in India Through its editorials and articles, he has been advocating that large scale industrialization is the only solution of India's problems of poverty, unemployment and defence, and has directed the attention of the public to the necessity of nationalization of India's power resources, to the usefulness of research institutes on power, plant industry, and to the creation of national councils of industrial and scientific research His radical views and straightforward criticisms have not rendered him a *persona grata* either with the British officials who constitute the Central Government or with the Congress, but they are gradually finding acceptance with the public

Mr T A Joyce, O B E.

THE approaching retirement, to take effect early in August, is announced of Thomas Athol Joyce, deputy keeper in charge of the Sub Department of Ethnography of the British Museum (Bloomsbury) Mr Joyce was educated at Dulwich and Hertford College, Oxford He was appointed in 1902 to the staff of the British Museum in the Department of British and Medieval Antiquities and Ethnography, of which Mr (later Sir) Charles Hercules Read was then keeper Mr Joyce during the Great War was attached to the War Office on the General Staff (Intelligence), attaining the honorary rank of captain, and being awarded the O B E in 1918 In 1921, he was appointed deputy keeper of his department, and on its reorganization was placed in charge of the Sub Department of Ethnography in 1932 In his departmental work, he had specialized in the ethnography of the peoples of Africa and the antiquities of America His three books on the archæology of South America, Mexico and Central America, appearing between 1912 and 1916, in which the evidence available up to that time was analysed critically, secured his position as an authority among scholars in both the Old World and the New Consequently Mr Joyce was inevitably chosen to lead the expeditions sent by the British Museum to British Honduras in 1925 and succeeding years up to 1931, to excavate the ruined Mayan cities of that region In addition to a large number of contributions to the publications of learned societies and the more serious of the journals devoted to the arts, such as the *Connoisseur*, Mr Joyce was the author in collaboration with Mr E Torday, of ' Les Bushongo" (1910), of a valuable little book on Mayan Art (1927) and of the official guide to the ethnographical collections of the British Museum (1910) He held office as honorary secretary of the Royal Anthropological Institute in 1903–13, for two terms as vice president, and as president (1931–33), and was president of the Anthropological Section of the British Association in 1934

Memorial to Dr. W. J. S. Lockyer

ON July 16, at the Norman Lockyer Observatory, Sidmouth, a memorial was unveiled to the late Dr W J S Lockyer, who was director of the Observatory, in succession to his father Sir Norman Lockyer from 1920 until his death in 1936 The unveiling was performed by Sir Francis McClean, a personal friend of Dr Lockyer, well acquainted with the latter s manifold activities, such as photography and aeronautics in addition to his astronomical work Sir Robert Mond took the chair, and a speech was also made by Sir Richard Gregory who, after paying tribute to Dr Lockyer s memory, spoke about the foundation and present position of the Observatory The memorial (subscribed for by friends of the late director) consists first of a panel with a portrait of Dr Lockyer in the centre surrounded by smaller portraits of those friends who have assisted in the administration and organization of the Observatory during his term of office Beneath this panel is a cabinet containing Sir Norman Lockyer s insignia and other records of his life and work As the subscriptions were more than sufficient to supply these two articles the balance was put towards the new Oxford' recording microphotometer (mentioned in NATURE of July 16 p 108), which thus forms a part of the memorial, very suitably recognizing Lockyer s astronomical work at the Observatory Half the cost of the microphotometer is being met by Sir Robert Mond and the other half by subscriptions to the memorial and from Observatory funds The instrument is now completed and installed so that the Observatory s equipment for measuring spectra is now brought up to the level of the principal observatories in Great Britain and other countries

Record Non-Stop Formation Flight

LEAVING Cranwell at 4 15 a m on Thursday July 7, four Vickers Wellesley aircraft, fitted with Bristol Pegasus engines and Rotol constant speed airscrews, flew non stop for 32 hours They arrived at Ismailia, Egypt, next day at 12 10 p m , having covered a distance of 4,300 miles at an average ground speed of 135 m p h This achievement, which was part of the development work of the Long Range Unit of the Royal Air Force, is the longest non stop formation flight ever accomplished A flight of this nature is an extreme test of the absolute reliability of the engines The Pegasus engines employed were the medium supercharged type, specially developed for economy of fuel consumption They have to be capable of running continuously on very weak mixtures, which increases the flame temperatures in the cylinders, so that the pistons, valves, plugs, etc , are subjected to abnormally high thermal stresses The average height during the flight was about 10,000 feet, which sets up a difficult combination of high engine gas temperatures and low air density on one hand and operation at very low power in a cold atmosphere on the other It is a tribute to the design, manufacture, and maintenance of these engines that they stood up to the exacting conditions of this flight, giving a continuous performance of more than a thousand horse-power for little more than a thousand pounds weight

'Round-the-World' Flight in Northern Latitude

Mr Howard Hughes, with Messrs Connor and Thurlow, navigators, Stoddart, radio operator, and Lund, engineer, landed at New York on July 14, at 7 37 B S T after having flown a circuit of the earth in the northern hemisphere, well above latitude

Ultracentrifugal Examination of Serum from the Lower Classes of Vertebrates

SOME time ago, a systematic investigation of the sedimentation constants of the respiratory proteins throughout the animal kingdom was carried out in this laboratory[1] with the view of finding possible relations between biological kinship and the properties of respiratory proteins

For the vertebrates, the following results were arrived at Hæmoglobin of practically the same sedimentation constant 4 4 (all sedimentation constants are given in units of 10^{-13}) corresponding to a molecular weight of 68,000 was found in the five higher classes, namely, Mammalia Aves Reptilia Amphibia Pisces A respiratory protein of the erythrocruorin type, known to occur in invertebrates and possessing a sedimentation constant of 2 0 corresponding to a molecular weight of 17,000, a quarter that of hæmoglobin was met with in the lowest vertebrate class Cyclostomata

A comparative study of serum from the various classes of the vertebrates was planned in order to discover whether the regularities found for the respiratory proteins would be reflected in the properties of the serum proteins For various reasons, this investigation was postponed until recently

The sera of various mammals (man horse cow pig and rabbit) have been subjected to detailed investigation by means of the ultracentrifugal method[2] In diluted sera, two principal components with sedimentation constants, s 4 5 and 7 1, were found, corresponding to an albumin of molecular weight $M = 69{,}000$ and to a globulin of $M - 160\,000$, respectively A higher globulin component of $s - 18$ and M of about six times that of normal globulin often occurred

The serum of Aves (hen) give the same general sedimentation diagram as that found for the mammals[3] We have recently made some preliminary runs on sera from the classes Reptilia, Amphibia, Pisces and Cyclostomata with the following results The sedimentation diagram shows in the case of Reptilia (snake), Amphibia (frog) and Pisces (*Abramis brama*) the existence of a component corresponding to the albumin of the higher vertebrates and two components which probably correspond to the globulins The serum from Cyclostomata (*Lampetra fluviatilis*) however is definitely different A component of s 3 5 and another of s 12 predominate The former probably has a molecular weight about half that of the serum albumin of the higher vertebrates

The measurements carried out so far seem to indicate therefore that on the whole the protein components in the sera from Mammalia, Aves Reptilia Amphibia and Pisces are similar with regard to molecular state while those from Cyclostomata differ considerably in this respect

A more detailed account of the investigation will be given elsewhere

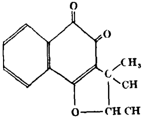
A New Natural Colouring Matter of the Naphthalene Group

S SIDDIQUI has recently described[1] the isolation of three new colouring matters, occurring together as a reddish dust on the leaves of *Didymocarpus pedicellata* In view of this publication, we now place on record the preliminary results of work in progress on the constitution of a colouring matter different from, but perhaps related to, Siddiqui s, and occurring as a deposit on the leaves and inflorescences of *Streptocarpus Dunnii* Mast , a member of a genus closely related to *Didymocarpus*[2]

The new pigment for which we propose the name *dunnione* crystallizes in orange red needles m p 98 99° from light petroleum or water and has the molecular formula $C_{15}H_{14}O_3$ Its physical and chemical properties and the results of degradative experiments including the formation of phthalic acid in oxidation processes show it to be a β naphtha quinone derivative The third oxygen atom is neither hydroxylic nor ketonic and the behaviour of dunnione towards alkalis indicates that the oxygen atom is a member of an easily ruptured chromane or coumarane ring Acidification of the alkaline solution obtained under certain conditions does not regenerate dunnione but a new substance which is probably an α naphthaquinone derivative The formation of acetaldehyde by oxidation with alkaline hydrogen peroxide and the amount of acetic acid (1 6 mol) produced on oxidation with chromic acid suggest that dunnione is 2 3 3 trimethyl 6 7 benzocoumarane 4 5 quinone (I) or the isomeride with the gem dimethyl group directly attached to oxygen



(I)

This is supported by the close agreement of the properties of dunnione and 2 3 dimethyl 6 7 benzocoumarane 4 5 quinone which has been synthesized by Fieser[3]

A more complete account of this investigation will be published elsewhere

Hæmocuprein, a Copper-Protein Compound of Red Blood Corpuscles

THAT copper is present in human blood has been known since 1875[1] Its concentrations in the red blood corpuscles and serum of man and different animals at different ages, under normal and pathological conditions, have been estimated by several workers[2 3] Very little has been known however as to the state in which the copper is present in the blood

The object of this investigation was to ascertain whether the copper present in the red blood corpuscles of mammals is free as an inorganic salt or is combined with an organic substance

The mere fact that the copper cannot be removed from a solution of plasmolysed red blood corpuscles by a very prolonged dialysis makes the possibility of its presence in the form of an inorganic salt very doubtful That this copper is bound to a protein we are now able to demonstrate by isolating from the red blood corpuscles of the ox a pure crystalline copper protein compound

The main steps of isolation and purification of this compound are as follows Red blood corpuscles of ox after a thorough washing with salt solution are plasmolysed with distilled water and treated with an alcohol chloroform mixture The hæmoglobin free solution which is filtered off contains most of the copper present in the corpuscles This solution is treated with lead acetate the precipitate being eluted with alkaline phosphate dialysed and the impurities removed with tricalcium phosphate The clear solution is then precipitated with acetone dissolved in water fractionated by adsorption on alumina Cγ and dialysed The clear and distinctly bluish solution thus obtained on treating with alcohol becomes opalescent and on standing in the cold yields within a short time bluish crystals of a copper protein compound These crystals easily settle down forming a distinctly blue sediment The analysis of the crystals shows 14 35 per cent nitrogen 1 12 per cent sulphur and 0 34 per cent copper

The copper protein compound thus obtained for which we propose the name of *hæmocuprein* forms a fourth organic copper compound known in living organisms Of the three other compounds hæmocyanine and polyphenol oxidase are copper protein compounds while turacin is a copper uroporphyrin compound

We have found that in serum also the copper is present as a blue copper protein compound very similar to hæmocuprein Its identity with the latter will however be ascertained when this compound will be isolated in a pure state

A more detailed account of the purification properties and relationship of hæmocuprein to the copper of serum and tissues will be published elsewhere

A Hæmoglobin from Bile Pigment

WHEN a solution of hæmoglobin and ascorbic acid in alkaline phosphate or in phosphate buffer of *p*H 7 6 is exposed to air at 20° for 48 hours the solution shows an absorption band in the red (at about 674 mμ) On reduction by hyposulphite, this band is replaced by a strong band at 629 mμ[1] By denaturation of the globin by alkali or pyridine, a hæmochromogen with an absorption band at 619 mμ is obtained The latter is identical with the α pseudohæmoglobin of Barkan and Schales[2]), in the preparation of these authors the denaturation is caused by the strong alkalinity of the cyanide solution

At higher temperatures the conversion of hæmoglobin to these substances is much more rapid but the oxidation of the prosthetic group is accompanied by a progressive oxidative denaturation of the globin part of the molecule This causes at first the formation of an alkali soluble green precipitate and ultimately of alkali insoluble compounds In such products[3] the prosthetic group becomes condensed into the denatured protein so that it can no longer be removed. Splitting with amyl alcohol and mineral acids results in pigments still containing peptide residues.

We have been able to remove the prosthetic group from the undenatured compound and to isolate the iron free compound in the pure state. The solution displaying the band at 629 mμ is precipitated by ammonium sulphate and the precipitate is digested with a mixture of two parts of ethyl acetate and one part of glacial acetic acid. This solution is diluted with ether, washed and filtered. It contains some protohæmatin, but no longer the hæmatin which gives the hæmochromogen with the band at 619 mμ. One per cent hydrochloric acid extracts biliverdin hydrochloride, while a weakly basic biliviolin is extracted by 25 per cent hydrochloric acid. From the first extract we have prepared crystalline *biliverdin* and *biliverdin dimethyl ester* and have identified the latter with an ester prepared from bilirubin by melting point and mixed melting point (216° F. on the copper block), crystal forms and other properties. The nature of the splitting products and the readiness with which iron is split off under conditions in which no trace of porphyrin or bile pigment is obtained from crystalline hæmin, prove that the prosthetic group of the new hæmoglobin is a bile pigment iron compound, closely related to verdohæmatin[4] while the fact that its hæmochromogen differs from verdohæmochromogen shows that it is not verdohæmatin. The name choleglobin is suggested for the new hybrid hæmoglobin, and the name cholehæmochromogen for its hæmochromogen.

At present we are unable to say in which way the prosthetic groups of choleglobin and of verdohæmochromogen differ in constitution. Choleglobin is readily obtained by the action of dilute hydrogen peroxide on a solution of hæmoglobin containing ascorbic acid; hydrogen peroxide thus plays a part in the formation of choleglobin similar to that in the formation of verdohæmochromogens from hæmochromogens[5], but the qualitative influence of the globin in the constitution of the prosthetic group arising from hæm on oxidation is remarkable.

It is of interest to compare the properties of the new hybrid hæmoglobin with those of hæmoglobin. It appears to unite with oxygen and with carbon monoxide reversibly. The compound with the band in the red appears to be oxycholeglobin, since it can be transformed into choleglobin by evacuation even after removal of all reducing substances by dialysis, and since it is reformed by aeration. Carbon monoxide choleglobin and carbon monoxide cholehæmochromogen possess the same absorption band (at 629 mμ), as do carbon monoxide hæmoglobin and carbon monoxide hæmochromogen, while they differ in their stability to oxygen. Whereas carbon monoxide cholehæmochromogen is readily decomposed on aeration, carbon monoxide choleglobin is only slowly converted to oxycholeglobin by oxygen. Incidentally, these observations prove again the identity of the prosthetic group in choleglobin and cholehæmochromogen. It is expected, however, that the carbon monoxide choleglobin band should coincide with that of reduced choleglobin. This fact complicates the investigation of the reaction of choleglobin with carbon monoxide, but the study of the conditions under which the band at 629 mμ appears in the absence and in the presence of carbon monoxide has satisfied us that carbon monoxide choleglobin exists.

A small amount of biliviolin is formed when oxygenated laked horse or sheep corpuscles are subjected to the treatment with the ethyl acetate glacial acetic acid mixture, while a somewhat larger amount of biliverdin is formed when the digestion mixture is added to the exhausted solution of laked corpuscles under nitrogen. While these experiments support the claim of Barkan and Schales that bile pigment hæmatin compounds occur in erythrocytes, we have been unable to find evidence for the presence of choleglobin in erythrocytes although our experiments show that choleglobin is very readily formed from hæmoglobin. Its absorption band at 629 mμ (shifted to 619 mμ on denaturation) becomes visible on addition of hyposulphite to oxygenated laked erythrocytes, but on reduction by evacuation or by hyposulphite in the absence of oxygen only a band in the red (at about 660 mμ) can be seen in addition to the band of reduced hæmoglobin (cf. also ref. [1]). The band in the red is not shifted on denaturation by pyridine, but it is abolished by oxygen or by carbon monoxide. It may therefore belong to the bile pigment hæmatin compound present in the erythrocytes, and to judge from its position it may be that of a verdohæmatin compound. These experiments, while still leaving undecided the exact nature of the hæmatin compound contained in bile pigment, leave little doubt that such compounds are intermediates in the breakdown of hæmoglobin.

The work described above has been carried out with a grant from the National Health and Medical Research Council of Australia.

Isolation of a Flavin-Protein Compound from Milk

WE have been able to prepare a flavin protein compound from cow's milk by the following procedure: (1) half saturation with ammonium sulphate of the whey of rennin treated milk; (2) ether extraction of the dried precipitate; (3) reprecipitation by 33 per cent saturation of the solution of the redissolved precipitate with ammonium sulphate at *p*H 4·0 and 0°; (4) elimination of the fraction insoluble in 25 per cent saturated ammonium sulphate at *p*H 4·0 and in presence of 10 per cent alcohol; (5) adsorption on and elution from alumina Cγ[1] followed by ultrafiltration and further fractionation with ammonium sulphate.

The orange yellow powder so obtained in a yield of about 1 gm. from 30 litres of milk dissolves to form a clear aqueous solution. The orange colour is discharged by addition of hyposulphite and restored by shaking with air. The absorption spectrum shows a broad band in the visible with a peak at 460–465 mμ. By treatment with 75 per cent methanol the coloured prosthetic group can be split off from the colourless protein. A solution of the prosthetic group shows the typical greenish fluorescence of flavin and also the reversible reduction with hyposulphite The absorption spectrum is practically identical with that of riboflavin[2] (peaks of the three absorption bands at 270 360 and 445 mμ respectively) The fact that the prosthetic group is insoluble in benzyl alcohol indicates that it is not riboflavin but more likely the corresponding phosphorylated compound[3]

Milk flavoprotein was found to catalyse the oxidation of reduced coenzyme I (prepared by reduction either with dehydrogenase systems or with hyposulphite) by carriers such as methylene blue, riboflavinphosphate and cytochrome *c* Calculation showed that in presence of a large excess of reduced coenzyme I each molecule of milk flavoprotein catalysed the oxidation by methylene blue of about a thousand molecules of reduced coenzyme per minute at 38° A positive catalytic effect was observed with as little as 0 02 γ flavin equivalent per *ml*

In the course of its catalysis milk flavoprotein did not appear to undergo a cycle of reduction and oxidation This consideration leads us to believe that milk flavoprotein acts catalytically not by serving as an intermediary between reduced coenzyme and the carrier but rather by forming a complex with the reductant and the oxidant and thereby facilitating the transfer of hydrogen

Since our best preparations contain only 0 06 per cent flavin contrasted to 0 6 per cent in the purest preparations of yeast flavoprotein the possibility still exists that the catalytic effects observed may be due to some persistent colourless impurity However the parallelism between catalytic activity and concentration of flavoprotein makes the impurity hypothesis unlikely

A New Enzyme of the Glycosidase Type

I SHOULD like to report the occurrence of what appears to be a new enzyme of the glycosidase type

This ferment which is readily prepared from celery seed using Tauber s technique [1] hydrolyses naringin the bitter glycosidic principle of grape fruit (*Citrus decumana*) *in vitro* at 37° and *p*H 7 The products are the insoluble aglycone naringenin (or naringetol) in crystalline aggregates belonging to the hexagonal system (I mention this because I have seen no reference to its crystalline form and have myself only succeeded in producing the amorphous form together with glucose and rhamnose by acid hydrolysis of naringin) and in addition a seemingly new disaccharide That this latter is not rutinose (β 1 rhamnopyranosido 6 *d* glucopyranose) follows from the work of Rabaté [2] whose results I have confirmed namely, that rhamnodiastase the enzyme which removes rutinose from its glycosides, will not decompose naringin Further since repeated attempts to hydrolyse naringin with emulsin have failed, it is probable that the disaccharide is akin to rutinose but has an α instead of a β linkage between its constituent sugars, or the only alternative, that it is glucosidorhamnose the aglycone linkage being through rhamnose instead of glucose

It is hoped to establish this definitely later on and meanwhile it is interesting to record yet another instance of the occurrence together in the same species but not necessarily in the same organ of substrate and enzyme which latter can be prepared from the leaves of the tree *Citrus decumana* again using Tauber s method The enzyme is absent from the rag peel and seeds of the fruit but occurs in small amount immediately between the flavedo and albedo where very possibly it plays some part in ripening since it is known that the bitterness then decreases in the fruit

It would seem therefore that this represents the first occasion on which naringin has been hydrolysed by an enzyme *in vitro* and possibly this new enzyme can be employed to study further the metabolism of rhamnosides in plants

Quantitative Measurement of Vitamin B_1 by the Thiochrome Reaction

IT has been known to us for more than a year that there is a large discrepancy between the results of biological vitamin B_1 assay and of determination of aneurin by the original method of Jansen[1] when both methods are applied to animal tissues We did not like to report on these observations before having succeeded in determining vitamin B_1 quantitatively by the thiochrome method Immediately after the publication of a paper by M A Pyke[2] however it was clear to us that he had estimated only a very small part of the total amount of vitamin B_1 actually present in the animal tissues investigated Dr Pyke s letter in NATURE of June 25 p 1141 prompts us to make the following remarks

Westenbrink and Jansen[3] described the determination of the two forms of vitamin B_1 known with certainty up to this moment aneurin and cocarboxylase or aneurin pyrophosphoric acid separately by means of the thiochrome method at the meeting of the Dutch Society of Physiology and Pharmacology of April 2, 1938 This method is based on the fact that thiochrome formed from aneurin is extracted quantitatively from the aqueous reaction mixture by isobutanol whilst the thiochrome pyrophosphoric acid formed from cocarboxylase remains quantitatively in the aqueous layer[4]

Since that time we have applied this method to various animal tissues When the tissues are finely minced and suspended in water and vitamin B_1 is absorbed on franconite at *p*H 3 the aqueous and isobutanol layers both show a blue fluorescence even without oxidation by ferricyanide In most cases this blank fluorescence is even stronger than the fluorescence observed after oxidation of the vitamin by ferricyanide However the blank fluorescence may be reduced to a very small remainder by digesting the tissue proteins by pepsin previous to the adsorption of the vitamin on franconite

After this observation we were able to carry out aneurin and cocarboxylase determinations in animal tissues Certainly the method is still capable of improvement but it was sufficiently accurate already to provide the following results

The aneurin content of animal tissues is very small as compared to their cocarboxylase content for example, normal rat's tissues liver 7–13 μgm cocarboxylase, less than 2 μgm aneurin, muscle 1 5 5 μgm cocarboxylase less than 0 5 μgm aneurin, kidney, 11 μgm cocarboxylase 0 5 μgm aneurin, brain, 6 μgm cocarboxylase less than 0 3 μgm aneurin The results obtained with normal pigeon s tissues were essentially the same Tissues of rats which had lived for three weeks on a diet free from vitamin B_1 only contain a very small amount of this vitamin, ten minutes after subcutaneous injection of a large amount of aneurin however, liver and kidney contained again a large amount of cocarboxylase besides an abnormally high amount of aneurin No increased amount of aneurin was observed in muscle and brain, hence injection of aneurin does not flood the whole organism with this substance

These investigations are fully described in a paper to be published in *Enzymologia*

We are much indebted to Prof K Lohmann of Berlin who kindly sent a specimen of crystalline cocarboxylase to Prof B C P Jansen director of this laboratory, whom we wish to thank for his interest in our work

Occurrence of Acetylcholine in Nervous Tissue of Crustaceans and its Effect on the Crab Heart

CONTRARY to the belief of certain investigators[1] [2] acetylcholine occurs in some tissues of decapod crustaceans in considerable amounts Trichloracetic acid extracts of leg nerves and ventral ganglia of *Carcinus* indicate a difference in the distribution of acetylcholine in these two tissues which is in close agreement with the distribution of choline esterase in the ventral ganglia and longitudinal commissures of the lobster, *Homarus* In this form it has been shown[3] [4] that two to four times as much choline esterase is present in the ventral ganglia as in the rest of the cord, which consists of fibres, with few if any, nerve endings In *Carcinus* there is approximately five times as much acetylcholine in the ventral ganglia as in the leg nerves

Studies of neuromuscular transmission in crabs[5] indicate that acetylcholine is probably not the mediator between nerves and skeletal muscle in these animals It has been found, however, to have a marked effect on the heart, and its action is the reverse of that on the vertebrate heart In low concentrations it increases the rate of beat of the isolated heart of *Carcinus* and *Maia*, and in high concentrations it produces tetanus and systolic stoppage The active material from 0 1 mgm of ventral ganglion or 0 5 mgm of leg nerve, per cubic centimetre of perfusion fluid, is usually sufficient to increase to more than double the frequency of beat of the isolated heart

Since adrenalin and acetylcholine both accelerate the decapod heart when administered in small doses, it is possible that the accelerator nerves to the heart normally produce one of these substances

A more detailed account of this work which was done at the Marine Biological Laboratory, Plymouth, and the Zoological Laboratory Cambridge, will appear elsewhere

Dormant Life of Tumour Cells in the Animal Body

WORKING with transplantations of Ehrlich mouse carcinoma (belonging to a strain cultivated *in vitro* in this Institute for nearly twelve years) we observed that tumours developed in general after two to four weeks These experiments were carried out on ordinary commercial white mice all of male sex The body weight was 13 20 gm In several cases we found however that tumours developed 6 weeks and even 8 10, 12 and 16 weeks after the inoculation of the carcinoma cells

These findings seem to be of interest in regard to The theory of the developmental physiology of malignant tumours recently put forward by A Fischer[1] From his experiments Fischer has drawn the following conclusion The cancer cell may already be present in the body and needs only what may be termed a realization factor in order to develop into a malignant tumour Such a factor may be, according to Fischer old age, chronic proliferative activity influence of hormones etc Our observations that cancer cells may lie dormant for a long period of time before they manifest themselves as a tumour, seems to support the theory of Fischer

The observation of a latent life of tumour cells for a period up to 16 weeks in the body of white mice may be significant in consideration of the fact that it amounts to one sixth of the whole life of a mouse In comparison with the duration of human life, it would mean a period of dormant life of tumour cells of ten years a period which is in very good agreement with our experience of the development of X ray carcinoma

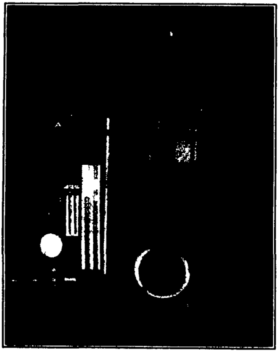
A Simple Respirometer for Small Animals

IN the course of some work carried on in this laboratory it became necessary to devise an apparatus that would measure oxygen consumption during the early life of the mouse Most of the available methods are either elaborate in technique and equipment or ill adapted for use with small animals However, a constant pressure type of respirometer, after the principle used by Winterstein and later described by

Dixon[1] has been successfully adapted to the problem and might well be given wider application Materials for its construction are readily available and it is so sensitive that determinations may be made over very short periods—½-4 minutes Mice are seldom absolutely quiet for longer periods, and so this sensitivity is almost a necessity when working with these animals

The constant pressure respirometer has not been widely used although its simple theory makes calculations extremely easy and calibration unnecessary It consists of a chamber and a recorder The carbon dioxide is absorbed by some suitable agent and the decrease in pressure resulting from consumption of oxygen is recorded on a sensitive manometer Mercury is forced into a calibrated pipette connected in the system until the manometer again records atmospheric pressure The amount of mercury entering the pipette in a given time can be read off directly and is equal to the volume of oxygen at the recorded temperature and pressure consumed by the organism The volume is then corrected to N T P



SIMPLE ANIMAL RESPIROMETER

The temperature of the chamber must be maintained accurately by a water bath thermostat and though the air in the recorder need not be at the same it must be kept at a constant temperature (recorded by thermometer *C*) It is convenient to maintain the room and water bath at the same temperature, for the animal can then be easily adapted in the room and readings taken soon after the respirometer is placed in the bath

The recording apparatus is arranged so that readings may be made at convenient time intervals until 3 c c of oxygen have been consumed Dry air is then sucked through the chamber for several minutes to restore the oxygen pressure As this air must be at the same temperature as the bath it is passed through an immersed copper coil before entering the chamber The loss of 3 c c of oxygen will not change the amount in the chamber by more than 1 2 per cent and such small changes in the partial pressure of oxygen have been shown to have little effect on oxygen consumption All readings are made in the 1 c c pipette *G* the mercury being controlled by the 1 c c syringe *E* As soon as the air in this pipette is exhausted, the mercury is lowered gradually, while 1 c c of air is drawn over at constant pressure from the 5 c c pipette *F* The mercury in *F* is controlled by syringe *D* This process is carefully carried out during a determination so no time is lost Manometer *B* contains kerosene stained with Sudan III The three way stop cock *A* allows the connexion of the chamber the recorder and the outside while equilibrium is attained and the isolation of the chamber and recorder during a determination The stop watch *H* is placed on the recorder for convenience Two or more chambers may be used with one recorder

The chamber of the respirometer is a 350 c c thin walled glass crystallizing dish fitted between two brass plates the top made water tight by a rubber gasket The chamber is protected by a sponge rubber base A round wire frame fitted with wire screening and having a diameter 1 5 in less than the chamber is placed inside The space between it and the glass wall is filled with fine mesh soda lime Concentrated sulphuric acid placed in a small vial absorbs moisture A hole is left in the wire net so that movements may be watched Within the chamber is placed a wire cage containing the animal The size of this cage depends upon the animal and should allow free movements though confined to a small space Cotton placed beneath the cage adds to the animal s comfort and absorbs excreta

The brass top is furnished with three outlets The central one contains a shaft with a propeller serving to keep the air of the chamber in motion The bearing if well greased through a small cup on the side will easily hold the slight differences in pressure which are allowed to exist during a determination A small flexible shaft or steel spring allows connexion with a motor, the speed of which can be carefully controlled through a rheostat 150 200 rev per min is sufficient and will not disturb the animal, but the speed used should first be shown to produce air currents small enough to have no effect upon the manometer

Another outlet provided with a stop cock leads to a suction pump which serves to ventilate the chamber Connexion to the recorder is by means of a second stop cock which can also connect the chamber through the copper coil to the outside The incoming air is dried with calcium chloride before it enters the coil

Readings for convenient intervals are taken until a sufficient number of checks give the experimenter confidence that he is dealing with a true basal state Movements usually produce enough heat to expand the gas in the chamber and affect the manometer so there is little chance of including the readings obtained during periods of movement in the final average

[1] Dixon Manometric Methods (1934)

Substitution of Cysteine for Protohæmin as the 'X' Factor for Growth of *H. influenzæ*

THE indispensability of iron in the form of protohæmin, the so called 'X' factor, to the growth of *H influenzæ* has long been an accepted fact Recently, the Lwoffs observed that the oxygen consumption of suspensions of this organism containing minimal amounts of hæmin is remarkably increased by the addition of small quantities of this compound Accordingly, they concluded that the 'X' factor functions by supplying, to the cell, material from which it can synthesize a catalytic respiratory system comprising cytochrome *C* and possibly cytochrome oxidase, peroxidase and catalase, although no direct evidence was advanced for the latter[1] If there is a correlation between the necessity of the hæmin for growth and its ability to promote oxygen consumption, it should be possible to grow the influenza bacillus by replacing the iron complexes with any other system which is capable of inducing oxygen consumption Since reversible oxidation reduction systems of suitable potential can function as efficient respiratory catalysts[2], we set out to determine the effect of these systems on the growth of *H influenzæ*

Those dye systems, within the potential range which has been demonstrated to be most effective in respiratory catalysis, failed to support growth when added to a basic medium to which adequate amounts of 'V' (yeast extract) were added Moreover, they actually inhibited growth even in the presence of the minimal amounts of protohæmin found necessary to support serial transfer (10^{-6} gm /c c) This inhibition was traced to the accumulation of hydrogen peroxide resulting from the activity of the supplementary dye catalyst

Since cysteine is effective in protecting cells from the inhibitory activity of peroxide[3], it should thus protect the organism from the inhibitory action of the dyes Experiments proved this to be the case Furthermore, cysteine plus suitable dyes effectively replaced hæmin as a growth requirement, and this combination supported growth in successive serial transfers Moreover, cysteine alone was found to be capable of permitting serial growth Whereas in the absence of hæmin, the sulphhydryl compound was required for aerobic growth, its presence was unnecessary for anaerobic growth This confirms the results of Anderson[4] who found that only the 'V' factor is required under anaerobic conditions

Since anaerobic growth can occur, it is evident that oxygen consumption is not essential for multiplication Further, since respiratory catalysts (dyes) alone cannot support growth, it is obvious that the 'X' factor cannot be replaced by a system which functions solely as a respiratory mechanism However, since cysteine alone can replace hæmin, and, in the latter's absence, is necessary for aerobic but not for anaerobic growth, it becomes probable that the sole necessary function of either of those substances is to provide the organism with a mechanism for protection against hydrogen peroxide, formed under aerobic conditions through the activity of a non hæmin respiratory system Thus, *H influenzæ*, in the absence of the 'X' factor, is physiologically similar to *E coli* in the presence of cyanide and methylene blue[5], since both organisms, under these conditions, possess mechanisms for the formation of peroxide but none for its destruction The role of hæmin is to supply this missing mechanism in the form of catalase. These experiments do not deny the role of hæmin in promoting respiration, but merely point out that such a function is unnecessary and incidental to its principal action

The foregoing results will be presented in more detail elsewhere

Composition of the Aerial Insect Fauna up to 300 ft.

IN a recent letter in NATURE (April 2) on the aerial drift of insects up to 2,000 ft , Hardy and Milne make reference to the intensive study of such drift at lower levels by flying 3 ft diameter nets simultaneously (usually for 3 hours round about midday) at heights of 277 ft 177 ft and 10 ft , on each of three masts placed along a 5/6 mile frontage at the Beam Wireless Station, Tetney, North Lincolnshire A brief note of the principal findings may be of interest

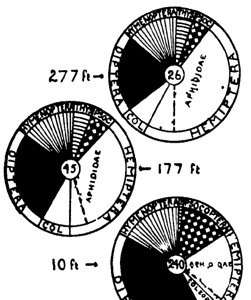
Thirty one series of collections were made from March until November during 1934 and 1935 yielding 2,896, 4,740 and 15 659 insects belonging to 166, 197 and 298 species at the top, middle and bottom heights respectively, a total of 23,295 insects of 421 species Most were winged adults of small size , but a number of nymphs (Hemiptera) and true apterous forms (Collembola and Psocoptera), in addition to 134 spiders (20 species) and parts of plants (31 species) were taken Species of seven genera made up more than 50 per cent of the numbers collected *Brevicoryne brassicæ* L (cabbage aphis) (3,334 individuals), *Sciara* spp (2,484), *Pterodela pedicularia* L (2,357), *Oscinis* spp (frit flies) (1 708), *Aphidius* spp (1,522) *Leptocera* spp (967), *Limothrips cerealium* Hal and *denticornis* Hal (corn thrips) (402)

The average 'density of insect population', defined as the number of insects in one million cubic feet of air, declined with height, so that 75 per cent of the total population was below 100 ft Diptera was the most numerous order up to that height and Hemiptera above Aphididæ were the dominant family at all heights The average composition of the fauna at each height is shown in the accompanying diagram

The distribution of population across the front was even although local aggregations occurred in nets, especially at ground level, often owing to the close proximity of host plants upwind The greatest numbers and variety occurred during the months of June and September, when insects are most active in breeding and dispersal.

The most favourable conditions for the maximum numbers in the air varied from family to family, but in general the greatest numbers of all insects occurred at relative humidities below 59 per cent, at surface wind velocities below 9 m p h. and at temperatures above 64° F the latter factor exercising most control

In addition to the pests already mentioned others also taken up to 277 ft were *Myzus* spp *Anuraphis padi* L (leaf curling plum aphis) *Kakothrips robustus* Uzel (pea thrips) *Cicadula sexnotata* Fall *Psyllia mali* Schmidt (apple sucker) *Macrosiphum granarium* Kby (grain aphis) *Anuraphis roseus* Baker (rosy apple aphis) *Phyllotreta undulata* Kutz and *Chaetocnema concinna* Mm (flea beetles) *Sitona lineata* L (pea and bean weevil) *Apion flavipes* Pk (clover seed weevil) *Chlorops taeniopus* Mg (gout fly) *Tipula paludosa* Mg (cranefly) and many others in small numbers to a total of 44 species



AVERAGE COMPOSITION OF THE AERIAL FAUNA AT 277 FT 177 FT AND 10 FT THE AVERAGE DENSITY OF POPULATION IS SHOWN AT THE CENTRE OF EACH DIAGRAM

The presence of large numbers of insects in the air throughout the greater part of the year indicates the important part played by wind carriage in their dispersal The observations also invite speculation as to the efficiency of ground quarantines in preventing the widespread distribution of insect pests

The work was initiated by Prof A C Hardy and carried out by me under his direction during part of the tenure of an agricultural research scholarship of the Ministry of Agriculture and Fisheries A full report will be published elsewhere

A New Test Plant for Potato Virus Y

HITHERTO the most convenient test for the presence of potato virus Y (*Solanum* virus 2) has been by sap inoculation to tobacco and no plant has been recorded on which the virus produces local lesions visible without decolorizing the leaf and staining with iodine While investigating the host range of potato viruses on solanaceous plants it was recently found that virus Y induces abundant brown circular local lesions about ten days after inoculation to leaves of *Lycium barbarum* seedlings When these lesions are very numerous they are followed by wilting and abscission of the inoculated leaves but no systemic infection of the plant results The latter fact was confirmed both by inoculation to tobacco from the non inoculated portion of the *Lycium* plant and by grafting it to healthy potato varieties highly susceptible to virus Y The characteristic local lesions resulted from inoculation with standard virus Y with a slightly different strain recovered from *Schizanthus*[1] and with virus HY II[2] and were freely induced by strains of Y no longer readily sap inoculable to tobacco Sap from Y infected potato tobacco and *Schizanthus* plants proved equally effective

No other virus so far tested has induced a similar reaction although faint local rings may result from inoculation of *Lycium* with necrotic strains of viruses X and B No visible lesions result from inoculation with weak strains of X or with potato viruses A F G and the virus of cucumber mosaic A rather bright yellow mottling of the leaves follows infection with tomato aucuba mosaic and this virus was readily recovered from the inoculated leaves There is no evidence of systemic infection of *Lycium* with any of the above viruses Inoculation to *Lycium* cannot be used to separate virus Y from a mixture of X and Y The effect of virus A on *Lycium* was tested by inoculation from an infected potato plant a host from which it is not readily sap transmissible the other viruses were taken from infected tobacco plants

It is possible that the reaction may prove of value as a test for virus Y, especially when that virus is present in plants other than tobacco

The Florisbad and Taungs Skulls

GOOD wine needs no bush nevertheless South African anthropologists are very grateful to Sir Arthur Keith for his unfailing interest in their work and particularly for his recent note on the Florisbad skull[1] It is as Sir Arthur says an outstanding landmark in human palæontology and well worthy of sharing attention with Rhodesian man But just as there is little agreement about the exact position of the latter in the human scale so the status of Florisbad man is not yet settled

Sir Arthur takes the same view as one South African school and regards Florisbad man as the successor of Rhodesian man and the immediate forerunner of Boskop man There is a good deal to be said for the first part of this contention as the brow ridges of the Florisbad skull are only a little less massive and they have only a slightly shorter span than the Rhodesian torus I find it difficult, however to link this feature with the vertical forehead of the Boskop skull as the doyen of British anatomists has gone on to do

Elsewhere[2] I have elaborated the thesis that Florisbad man is of lower rank than Rhodesian man, and that he is an African variant of the Neanderthal race of Europe This view is supported by the fact that as regards his cranium and brain cast he is *morphologically identical to the type* Neanderthals of Europe On the other hand I admit that his face although more massive and prognathous than in any of the Neanderthals, has a deep sapient dip in it beneath the cheek bones We must not let ourselves be carried away, however, by the idea that there was only the one European race of Neanderthals His characteristic Moustierian culture, which has as close an association with this physical type as any known culture has with human form is very widespread over the world, and I myself have picked up several Moustierian points on the veld bearing all the hall marks of the very special technique employed in making these stone implements It is therefore a really very significant argument in favour of my view, when I state that the stone implements found associated with the skull in the Florisbad zone present a typical Moustierian facies[3] Seeing that we have no objection to accepting the Neanderthaloid Australian Bushman as one of the races of *Homo sapiens*, there can be no valid reason for rejecting a slightly sapient South African Neanderthal as a member of this latter species provided it can be shown that the major facts of his anatomy point that way

In any discussion of human morphology the question arises as to what characters are to have most stress laid on them and as to what is to be our final criterion of advancement or retardation in the human scale We have to decide whether it is to be the cranium with the underlying brain or the teeth and jaws which go to make the face that we are to rely most upon There are enough data now to show that anthropologists cannot have it both ways The Piltdown discovery put an end to the face as a criterion, for no one regards this type as anything but a man, in spite of his chimpanzee like jaw and teeth The same applies to the latest discovery of the adult *Australopithecus*[4] Notwithstanding his human type of dentition, more human in some respects than that of both Piltdown and Peking man, Broom sums him up as 'a chimpanzee with human teeth" In doing so, Broom is tacitly laying stress on the brain of *Australopithecus*, which he seems still to assume to be that of a chimpanzee, as so many other distinguished anthropologists have already done For my part I do not consider the brain of the Taungs infant to be that of a chimpanzee In a recent comparison which I have made between the brain cast of this fossil and the brain and brain cast of a chimpanzee of the same age I have been impressed by the great difference between them In Fig 1 I show how the linear contour of the cerebrum and cerebellum of the Taungs infant outstrips that of this chimpanzee The surface of the brain cast of the former shows an equally striking superiority in the size and salience of its convolutions over that of the latter The comparison I have drawn is not an isolated one and in Fig 2, I demonstrate how much more advanced the brain of the Taungs infant is beyond that of a slightly older chimpanzee, which it exceeds in bulk by 50 per cent I have made other comparisons which show that the brain of the infant *Australopithecus* outclasses that of a gorilla of the same age, and that the mental endowment of this tiny creature can quite hold its own with even that of a huge adult gorilla

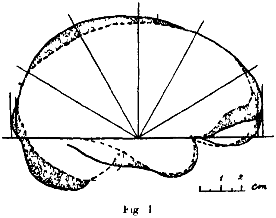

Fig 1

CONTOUR OF THE TAUNGS ENDOCAST SUPERIMPOSED ON THAT OF A CHIMPANZEE OF THE SAME AGE THE STIPPLED AREAS INDICATE THE EXTENT TO WHICH THE FORMER EXCEEDS THE LATTER IN SIZE

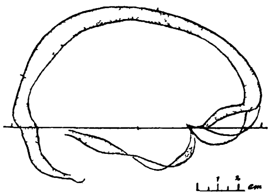

Fig 2

CONTOUR OF THE ENDOCAST OF *Australopithecus africanus* SUPERIMPOSED ON ONE OF A CHIMPANZEE WITH A CRANIAL CAPACITY OF 335 C C THIS CHIMPANZEE WAS A YEAR OLDER THAN THE TAUNGS INFANT, YET ITS BRAIN WAS INFERIOR TO THE EXTENT INDICATED BY THE STIPPLED AREA

The most noticeable advance in the brain of *Australopithecus africanus* is in the region behind the bregma (vertex), in the same place as all the main subsequent human advances have been made His superiority over the chimpanzee in the cerebellar region is also very striking With such knowledge of cerebral localization as we already have, it is fairly safe to interpret this parietal enlargement of the association area, located behind the sensory and motor areas for the leg, and this cerebellar hypertrophy as being expressive of the human divorcement of the legs from the hands From now on, the limbs had separate functions to perform and new machinery for their independent co ordination Arboreal habits were good enough to make a four handed primate out of something else, but it took the open veld to make the first human toddler, now properly on his legs and free to use his hands for better handiwork—and occasional mischief Even if we discount his human dentition entirely, which it would be rash to do, this surely is an upward step

It seems to me, therefore, that many pronouncements regarding this unique South African fossil will have to be revised, and in fact that we cannot do better than go back to Dart's first classical description of it as published in NATURE of February 7, 1925

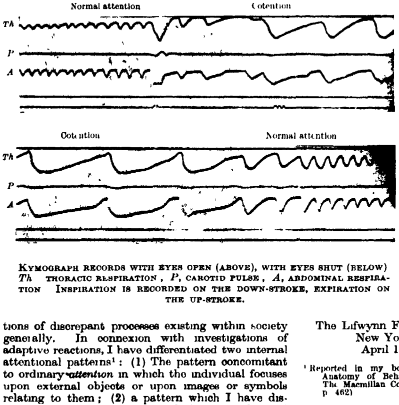
Kymograph Studies of Physiological (Respiratory) Concomitants in Two Types of Attentional Adaptation

THE group or phylobiological researches which I have carried out in the field of behaviour-disorders indicate that the neuroses and psychoses are aggravations of discrepant processes existing within society generally. In connexion with investigations of adaptive reactions, I have differentiated two internal attentional patterns[1]: (1) The pattern concomitant to ordinary *attention* in which the individual focuses upon external objects or upon images or symbols relating to them; (2) a pattern which I have distinguished as *cotention*, in which the individual focuses upon tensions located predominantly in the region of the eyes or in the segment of the symbolic activity



KYMOGRAPH RECORDS WITH EYES OPEN (ABOVE), WITH EYES SHUT (BELOW) *Th* THORACIC RESPIRATION, *P*, CAROTID PULSE, *A*, ABDOMINAL RESPIRATION INSPIRATION IS RECORDED ON THE DOWN-STROKE, EXPIRATION ON THE UP-STROKE.

The second pattern precludes the usual play of phantasies and the customary affects and strivings commonly adhering to mental imagery. Instead there is sensed the organism's generalized tensions as contrasted with the more specifically localized tensions of the symbolic segment The competitiveness and self-concern characteristic alike of so-called normal and neurotic attitudes are eliminated, and there occurs a re-centring of interest which gives precedence to internally motivated, phyletically co-ordinated trends. Physiological (neuromuscular) modifications related to the organism's phantasy sphere have thus been differentiated from physiological modifications concomitant to the organism's direct relation to environmental reality

Recent instrumental experimentation shows that the pattern of cotention is characterized by a scarcity of eye- and lid-movements and by specific changes of respiration, namely, (*a*) a markedly decreased frequency, (*b*) an increased amplitude of the respiratory movements, and (*c*) in certain subjects a decreased inspiration-expiration ratio. The respiratory curve, as obtained by thoracic and abdominal pneumographs, was recorded by the wax paper kymograph devised by Volkmann and Gerbrands (Harvard). The diminution in frequency was from a normal average of 12 8 to an average of 4 2 respirations per minute during cotention

It was possible to differentiate these respiratory alterations sharply from other slight modifications occurring under varying conditions of mental rest or activity The respiratory changes may be considered as part manifestations of the two types of attentional adaptation They set in immediately with the altered attention, they occur automatically, and they are not affected by opening or closing the eyes

The differentiation of the two forms of attention is of special interest in relation to the problem of behaviour disorders Under conditions of cotention, symbolic projections possessing the emotionally coloured content characteristic of neurotic reactions are automatically arrested The cotentive reaction may be brought about by training Experimentation with respiratory changes is being continued in the laboratory of the Lifwynn Foundation, and other physiological patterns which underlie the two types of attentional adaptation are being investigated

Chromosome Structure

IT was recently shown[1] that the somatic chromosomes of *Trillium* are composed of four strands intertwined in pairs at metaphase, while in anaphase and telophase they contain two spirally twined threads.

Recent cytological investigations of *Crocus sativus* (saffron) yield further crucial evidence regarding chromosome structure. This cultivated form is triploid, having 24 somatic chromosomes From preparations of root tips, three of these chromosomes are seen in anaphase (Fig 1*a*) to have a satellite attached to their long arm As this material was fixed in Navashin, the split in the chromosomes does not show at this stage, and the satellites also appear as single structures These satellites, as well as the chromosome, are, however clearly seen in early telophase (Fig 1*b*) to be double

By a special staining method recently devised[2] it has been possible to stain the chromosomes and the nucleolus differentially, so that the nucleolus can be picked out at its very beginning in telophase in contrast with the chromatin, and the thread attaching the satellite to the chromosome can be shown to be composed of chromatin By a special method of mordanting the chromosomes are stained red with Feulgen and the nucleolus light green This staining method has also been applied to root tip smears[3] making possible an investigation of the precise relationships between nucleolus, satellite, connecting thread and chromosome in various plant genera during both the somatic and the meiotic divisions

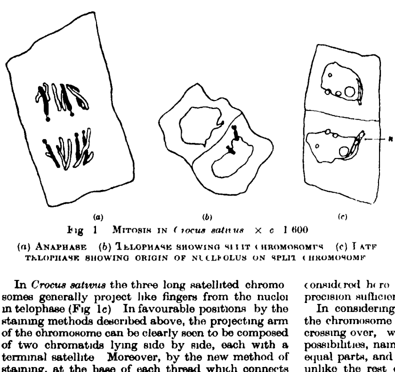

Fig 1 MITOSIS IN *Crocus sativus* × c 1 600

(*a*) ANAPHASE (*b*) TELOPHASE SHOWING SPLIT CHROMOSOMES (*c*) LATE TELOPHASE SHOWING ORIGIN OF NUCLEOLUS ON SPLIT CHROMOSOME

In *Crocus sativus* the three long satellited chromosomes generally project like fingers from the nuclei in telophase (Fig 1*c*) In favourable positions by the staining methods described above, the projecting arm of the chromosome can be clearly seen to be composed of two chromatids lying side by side, each with a terminal satellite Moreover, by the new method of staining, at the base of each thread which connects the satellite to the (red) split chromosome can be seen a minute green granule which represents the beginning of the nucleolus Each nucleolus thus arises as two bodies close together, one on each of the twin threads of a telophase chromosome, showing conclusively the double structure of the chromosome at this time As these nucleolar rudiments grow, they shortly fuse into one globular body, which then grows to the full sized nucleolus of the resting nucleus

It may be pointed out that Dearing[4] has shown essentially the same thing in the salamander *Amblystoma*, the telophase chromosomes being double and the nucleolus arising from the satellited chromosome as two granules, one on each chromatid The present method of staining, by which the nucleolar material is green while the chromatin is red, makes it impossible to mistake the beginnings of the nucleolus for chromomeres

Distribution of Crossing-Over in the Chromosomes of *Drosophila*

FROM an analysis of crossing over in *Drosophila melanogaster*, I was led to certain conclusions concerning the distribution of the chiasmata, or points of exchange along the cytological chromosomes[1] In particular I noted that the centromere or spindle attachment showed certain peculiar relations to the regional frequency of crossing over, and I advanced the hypothesis of a time sequence in the occurrence of chiasmata (moving away from the centromere) to account for these observations

This has recently been challenged by Charles[2] in an analysis of crossing over in the X chromosome of *Drosophila* He finds that crossing over has certain similar relations with the attachment end and with the free end of this chromosome He concludes that the observed phenomena could be explained as well or better, by relating the frequency of crossing over to both ends jointly Such a relation he says would account for all the evidence that I have adduced for the special relation to the spindle attachment He also proposes certain alternative hypotheses which, however will not be considered here as they are not formulated with a precision sufficient to allow of prediction

In considering Charles's claim that both ends of the chromosome play a part in the determination of crossing over, we must distinguish between two possibilities, namely, that they play equal or nearly equal parts, and that they both behave in a manner unlike the rest of the chromosomes but that their roles are not the same The former would appear to be the alternative advocated by Charles This, however, cannot be true, as it allows of no explanation of the special properties of the attachment region in the effects of age, temperature and similar agencies on variations in crossing over Nor does it allow of an explanation of the findings of Sturtevant and Beadle[3] with regard to the effect on crossing over in the *X* chromosome of heterozygosity for the Delta 49 inversion These authors observed that in such a system crossing over is considerably more affected, in the regions of normal sequence, distal to the inversion than in similar regions proximal to the inversion Finally Charles's own figures, notably his Fig 1, show asymmetry of the crossing over frequency distribution along the salivary chromosome, though this type of map (as compared with the mitotic map which I consider to be more suitable for such studies) would tend to minimize such asymmetry Similar skewness is to be observed from a number of other sets of data published by various authors Thus we may exclude the possibility that the attached and free ends have precisely similar properties in crossing over

In considering the alternative that both ends of the chromosome have properties unlike those of the central regions, but that the two ends do not behave alike, we are in effect discussing my original conclusion A terminal region may be expected *a priori* to behave differently from the central regions if only because it is an end But the different behaviour of the two ends is not to be anticipated in such a way, and inasmuch as the attachment end differs very markedly from all other regions, we must endeavour to account for its behaviour by giving it a special role in the process of crossing over This I attempted to do by the hypothesis of the time sequence in chiasma formation The virtues or shortcomings of this hypothesis as an explanation of the observed unique behaviour of the attachment region cannot be considered here, but new data, bearing on the question, will be discussed elsewhere in detail

Control of a Species-Difference by Means of a Difference in an Inductor

Hitherto, experimental analyses of species differences by the use of xenoplastic transplantations have shown that the distinguishing characteristics are inherent in the tissues themselves This is especially true when one considers organs which owe their differentiation to induction from other parts The inductor of one species, although able to produce an effect on tissues of another species, acts only as a release mechanism calling forth certain potencies without impressing the characteristics of its own species on the reacting system

Xenoplastic transplantations between two species of *Drosophila* have yielded a different result The adult testes of *D pseudoobscura* are approximately ellipsoids, while those of *D azteca* are tubes wound up in form of a spiral of about one and a half turns Larval testes of both species are very short ellipsoids They attain adult shape after having become attached to the vasa efferentia, which originate independently of them Dobzhansky[1], in an analysis of gynandromorphs in *D simulans*, has pointed out that the spiral form of the testes in this species is probably due to some organizing influence exerted by the vas, as the testes, in spite of increase in volume, remain ellipsoidal if not attached to a duct This has been confirmed by numerous transplantation experiments involving five other species[2]

In order to test whether this 'induction' of adult form is of the nature of a release mechanism, to which the gonads respond according to their genetic constitution, reciprocal transplantations of larval gonads between *D pseudoobscura* and *D azteca* were made The shape of the implants was studied after the metamorphosis of the operated animals into adults It was found that the 'genetically spiral testes of *D azteca* assume an elongated ellipsoidal form if attached to a vas of *D pseudoobscura* and that the genetically ellipsoidal testes of *D pseudoobscura* grow into a spiral if attached to a vas of *D azteca* Here then, we are confronted with a case in which the structure of an organ of one species has been determined by a specific organizing influence exerted by tissue of another species The fundamental difference in testis shape between *D pseudoobscura* and *D azteca* is not a result of the genetic differences of these organs, but depends rather upon a difference in the constitution of the inductor, the vas efferens

The contrast between this and former results with xenoplastic induction loses some of its sharpness if we consider the probable nature of the organizing action on the shape of the testes Here we are not dealing with the induction of tissue differentiation, since the testis is already histologically differentiated, but with the distribution of growth processes A testis probably assumes a spiral form as the result of unequal growth in the length on two opposite sides of its surrounding membrane, while an ellipsoidal testis has undergone growth of equal intensity for all regions at any given level of its periphery It is suggested therefore, as a working hypothesis that the control of testis shape in these *Drosophila* species is the result of some growth influencing principle unequally distributed over the proximal parts of the vasa of *D azteca* as contrasted with a symmetrical distribution of such a principle in *D pseudoobscura*

Neutral Particles in Cosmic Radiation

A number of cosmic ray experiments seem to indicate the existence of a non ionizing penetrating radiation which is capable of producing charged secondaries and showers Barnóthy and Forró[1] have found that at a depth of 800 m water-equivalent, practically the whole ionization is due to shower particles and not to single ionizing rays From this fact they concluded that the shower producing radiation must be non ionizing, and owing to its high penetrating power they proposed to identify it with neutrinos

In a more conclusive way the existence of a neutral penetrating radiation is shown by the experiments of Maass[2] He measured the absorption of single cosmic ray particles by a counter telescope placing an iron block of varying thickness (A) between the counters and (B) above the top counter The difference of the number of coincidences $(B) - (A)$ must obviously be due to ionizing secondaries produced in the iron by a non ionizing radiation[3] The curve $(B)-(A)$ has a maximum at a thickness of 30 cm iron For higher thicknesses the curve decreases very slowly corresponding to an absorption of the primary neutral radiation The absorption coefficient ($\sim 9 \times 10^{-3}$ cm^{-1} iron) is practically the same as that of the charged penetrating component, which is now known to consist of heavy electrons The absorption coefficient of the charged secondary particles ($\sim 8 \times 10^{-2}$ cm^{-1} iron) is though about ten times larger than that of the primary neutral radiation still far smaller than that of ordinary electrons We therefore assume that the secondary particles are relatively slow heavy electrons

The fact that the absorption of the primaries is very similar to that of the heavy electrons suggests that they are of a similar nature Indeed it seems to be impossible to identify them with any other known neutral radiation Neutrons would have a much smaller penetrating power and there is no process known by which neutrinos could produce heavy electrons in sufficient large numbers We therefore think that we have to deal in these experiments with *the neutral counterpart of the heavy electron* for which we propose the name *neutretto*

The existence of such a particle has indeed been made very probable by recent theories of the nuclear forces[4] In these theories the heavy electron is made responsible for the exchange forces between a proton and a neutron The fact that the forces between two protons seem to be equal to those between a proton and a neutron requires the existence of a neutral particle which has the same mass and similar other properties as the heavy electron It has also been shown by Kemmer[5] that assuming equality of all the nuclear forces the neutral particle can be included in the theory in a very simple and natural way According to this theory, the behaviour of a neutretto would be very similar to that of a heavy electron Apart from those processes in which the charge is involved directly (ionization emission of light) the neutretto would give rise to all the same types of showers which heavy electrons can produce as discussed in a recent paper by one of us (W H)[6]

In particular a neutretto (denoted by Y°) can be transformed into a heavy electron $Y\pm$ during a collision with a proton (P) or neutron (N) and vice versa

$$Y^\circ + N \rightleftarrows P + Y^- \text{ or } Y^\circ + P \rightleftarrows N + Y^+ \qquad (1)$$

For an energy of the order 10^8 e v the theory leads to a cross section which would allow a neutretto or a heavy electron to travel a distance of the order 5 cm lead, 7 cm iron or half a metre water before such a transformation takes place[6] For higher energies, however, the processes (1) are replaced by the production of showers consisting of heavy electrons created in a single multiple process for example,

$$Y^\circ + P \rightarrow N + Y^+ + Y^- + Y^+ \text{ etc} \qquad (2)$$

The mean kinetic energy of the particles created in such a process is of the order of a few times the rest energy ($mc^2 \sim 10^8$ e v) For a given energy of the primary particle the mean number of shower particles is therefore also determined The cross section for the occurrence of such a process cannot however be deduced from the theory but the experiments show that it decreases with increasing energy thus leading to a high penetrating power of the heavy electron and neutretto

The experiments discussed above are quite consistent with these ideas In particular the curve obtained by Maass can easily be understood by the production of heavy electrons by neutrettos according to (1) and (2) The energy and penetrating power of the secondary heavy electrons to be expected in this theory (~ 7 cm iron) are just of the order obtained experimentally (~ 12 cm iron)

We think it likely that the neutretto is responsible for the majority of processes ascribed to neutral penetrating particles in cosmic radiation although of course the participation of neutrons or neutrinos cannot be excluded

Viscosity of Air and the Electronic Charge

I SHOULD like to be allowed to make two comments on the recent communication in NATURE of Dr C B Banerjea and B Pattanaik[1]—a letter giving the preliminary results of what is evidently a very accurate determination of the viscosity of air

First the generally accepted X ray value of the electronic charge is $4\cdot803 \times 10^{-10}$ E S U – not $4\cdot807 \times 10^{-10}$ Secondly there are now available the results of three independent and extended series of measurements on oil drops namely (1) the pioneer work of Millikan (2) the more recent work of Bäcklin and Flemberg[2] and (3) the very recent work of Ishida Fukushima and Suetsugu[3]

It is of considerable interest to combine the results of these three measurements with the value of the viscosity of air obtained by Harrington[4] in 1916 (the value used by Millikan) and with the more recent values of other workers and to calculate the resulting values of e

The values of the viscosity are (all in 10^{-7} poise and reduced to 23 C)

(*a*)	1822·6	(*d*)	1833·3
(*b*)	1834·8	(*e*)	1830·3
(*c*)	1829·2		

(*a*) is Harrington's value[4] (*b*) is the mean of two almost identical values obtained independently by Bond[5] and Kellstrom[6] (*c*) is due to Houston[7] (*d*) to Banerjea and Pattanaik[1] and (*e*) to Rigden[8] The results of the calculations are tabulated below e being given in 10^{-10} E S U

Oil drop Viscosity	(1) Millikan	( ) B and F	(3) I F and S
(*a*)	*4·770*	4·[illegible]52	*4·806*
(*b*)	4·818	*4·800*	4·854
(*c*)	4·796	4·7[illegible]8	4·832
(*d*)	4·81	4·[illegible]94	4·848
(*e*)	4·80[illegible]	4·[illegible]82	4·836
Means	4·[illegible]99	4·781	4·835

Mean of all sets together 4·8[illegible]5
(Italic values of e are those given by the authors)

Possibly the only justifiable conclusion to be drawn from all this is that the oil drop method (because of the many difficulties and uncertainties in its application) is not suitable for the exact determination of e It is of interest, however, to note that of the three available sets of oil drop measurements Millikan's work now appears to be in by far the best agreement with the X ray results In fact if we leave out Harrington's value for the viscosity (which seems certainly to be too low), and use the mean of the remaining values, Millikan's measurements give $e = 4\ 806 \times 10^{-10}$ E S U If we also omit Bond's and Kellström's values, which seem likely to be too high—that is, if we only use the most recent three measurements of the viscosity—Millikan's value becomes $4\ 803 \times 10^{-10}$—in exact agreement with the X ray measurements

Waves Associated with Moving Corpuscles

BY appropriate general treatment, it may be shown that solutions involving the path time are invariant that is can exist in any set of space co ordinates Starting then with the solution for the electron velocity ripple in terms of the transit half angle[1] it may be shown, by analogy with van der Pol's treatment of waves in *n* dimensions[2], that this ripple satisfies certain conditions The most important of these is that the ripple satisfies a five dimensional wave equation, the wave velocity being that of the particle, provided the frequency of the ripple is such that $\theta \gg \sqrt{2}$, where θ is the transit half angle ($= \omega\tau/2$) It will be convenient to regard this ripple as that part of the particle vibration which corresponds to free, as distinct from forced, oscillation The factor ½ must be associated with the fifth dimension as follows

$$\theta = \omega\tau/2 = \omega(t-t_1)/2 = \omega r_5/c_5$$

where c_5 is the velocity appropriate to the waves

I have confirmed that when no weight factor is involved the result of integrating transit time solutions over all possible values of θ (that is from θ = 0 to θ = ∞) leaves the four dimensional solution that would have been obtained had the transit time been taken as negligible Thus (i_c = electron convection current i = total current density (ripples)

$$[i_c]_t = ie^{i\omega t}\int_{\theta=0}^{\theta=\infty} \Upsilon_2\,(2i\theta)\,di\theta = ie^{i\omega t}\left|\frac{e^{2i\theta}-1}{2i\theta}\right|_0^{\infty} = ie^{i\omega t}$$

A Useful Statistical Test

THE method described below gives a useful criterion of the significance of the difference between an observed and a hypothetical frequency distribution Since it provides an exact test, it is particularly useful in the case of small samples, in which the expectation in some frequency classes may be very small It is only applicable when the number of possible samples containing the same number of observations as the observed sample is determinable The test answers the question Is this a reasonably likely sample to be obtained in a random draw ? It does not give the proportion of less likely samples which may be expected to arise, as does the χ^2 test

Let us suppose that the hypothetical population shows the following proportional frequencies in four classes

$$\tfrac{1}{8},\ \tfrac{3}{8},\ \tfrac{3}{8},\ \tfrac{1}{8},$$

the total being 8

The number (N) of possible samples of n with r frequency classes is given by

$${}_rH_n \text{ or } \frac{(r+n-1)!}{(r-1)!\ n!}$$

Thus the number of possible samples of 8 in 4 classes is

$$\frac{11!}{3!\ 8!}, \text{ or } 165$$

Clearly the average probability of the samples is $1/N$ or $1/165$ An observed sample having average probability cannot, of course, be considered as an unlikely sample to arise Half the average probability has been found to separate samples at about the 5 per cent point agreeing closely with χ^2 ($p = 0\ 05$) in cases where both tests are applicable It is only necessary therefore, to express p, the probability of an observed sample, as a fraction of $1/N$, considering the sample as unlikely to have arisen from the hypothetical population if Np is less than 0 5

For example, is a sample of eight having the frequencies 3 1 1, 3, likely to have arisen as a random sample from the population specified above ? $N = 165$, and p is given as a term in the multinomial distribution Thus

$$Np = 165 \times \frac{8!}{3!\ 1!\ 1!\ 3!}\ (\tfrac{1}{8})^3(\tfrac{3}{8})^1(\tfrac{3}{8})^1(\tfrac{1}{8})^3 \quad < 0\ 1$$

The sample is therefore very unlikely to have arisen as a random sample from the hypothetical population

The change in the number of possible samples with a change in r corresponds to a change in the number of degrees of freedom with the χ^2 test Other restrictions on variation such as the use of a calculated mean or standard deviation, do not change the number of possible samples at all in the same way This suggests that restriction in the χ^2 distribution is much more accurately allowed for by degrees of freedom in the case of differences in the numbers of frequency classes, than it is with restrictions imposed by the use of calculated statistics in specification of hypothetical populations

Passivity of Iron to Natural Waters

THE passivity of iron has been known for more than a century, but until recently interest has mainly been directed to treatments which render iron inert to copper salts such treatments do not necessarily prevent rusting by natural waters Three sets of observations in this laboratory have indicated how passivity to such waters might be obtained (1) The film present on iron rendered passive in chromate appears to be the air formed film with its weakest places fortified with chromium oxide[1], a 'patchwork' is not ideal for protection (2) The coarser the grinding of an iron surface, the longer the time needed to produce passivity[2] (3) Susceptibility to corrosion, as judged by statistical studies, varies from spot to spot and is influenced by chemical character[3]

These facts have suggested (*a*) preliminary abrasion followed by (*b*) the etching away of the shattered metal which is difficult to render passive, and finally (*c*) treatment in a solution containing chlorides and chromates in amounts adjusted to eat away specially susceptible spots whilst leaving the remainder passive (On pure iron, where there are no chemically different spots, chloride free chromate gives almost equally good results)

After such treatment specimens of iron or mild steel, 1 8 cm square have been preserved in various natural waters, and have only produced a rusty colour in the water after periods of the order of 100 times those required with untreated metal Thus soft moor land water which becomes rusty after about an hour s contact with untreated metal remains clear for several days if the metal has first been treated harder waters from chalk sources which acquire a rusty tint within a day from untreated metal have remained unchanged for some months in contact with treated metal But the expectation of escaping corrosion decreases with the specimen size and, although encouraging, the observations are not thought to possess immediate technical importance especially as the treatment does not prevent rusting by a polluted atmosphere

The behaviour of the passive iron to scratching is very interesting Iron covered with a *visible* oxide scale by heating and scratched locally before immersion often suffers intensified corrosion since the oxide scale acts as cathode of a cell which concentrates anodic attack on the small area of exposed metal but a specimen of iron rendered passive and then engraved with a scratch in the Mears Ward machine[4] (66 tons/sq in), has remained in Cambridge water for three months without appreciable change (similar iron not rendered passive produces rust within a day) A possible explanation—suggested by studying films transferred to celluloid, as described elsewhere[5]—is that, whilst the engraving of a scratch line causes a *thick* film to crack off, exposing the iron it tends to press a *very thin* film down into the groove, so that the metal remains largely covered Some interruption of the film is certainly unavoidable, but this will not necessarily cause corrosion if the interruptions are very small, since the anodic current density may then reach the value needed to restore passivity the largest gap which can be tolerated will depend on the composition of the water

Negative Thixotropy

Aqueous solutions of ammonium oleate are strongly elastic If given a rotary motion and then allowed to come to rest, the rotation is in part retraced before they do so In 1926, Hatschek and Jane[1] examined these solutions in a Couette type viscometer They found, *inter alia*, that when the outer cylinder was rotated at a constant angular velocity, the torque on the inner one, after a short period of normal magnitude increased to an irregularly fluctuating value many times greater After a period of rest the behaviour was repeated It appeared that a gelatinous structure was actually built up by the process of shear, and dissipated again at rest The subsequent discovery[2] that the anomalous increase of torque was associated with the onset of turbulence distracted attention[3] from this first conclusion It seems probable however that the turbulence itself also anomalous and of abnormal appearance[3], was another result of the structure built up rather than the direct cause of the increased torque

Solutions of many of the newer paraffin chain salts also show the phenomenon of elastic recoil, and in more pronounced degree, and similar behaviour in the Couette viscometer The observations now referred to were made mostly on a 0 02 per cent solution of the copper salt of cetyl phenyl ether sulphonic acid at 80- 90° C

A very simple experiment demonstrates what may be called the negatively thixotropic behaviour A slow stream of air bubbles of suitable size is introduced at the bottom of a large beaker full of solution They rise in normal manner and in normal time (for water) if the solution is undisturbed If the solution is now gently stirred round their upward course takes many times as long and is extremely irregular The bubbles frequently collect in small clusters and whether single or in clusters, they are seen to halt at or be diverted round invisible barriers About a minute after the stirring is stopped the normal behaviour is almost completely restored

Further evidence is found in experiments on flow through plugs of fibrous material, for example, glass wool, cotton wool or (at 60°) wool felt If a pressure difference is applied suddenly, after a period of complete rest the flow is at first about as rapid as with water but quickly falls to a steady value only a small fraction of that obtaining initially Pressure differences in excess of a somewhat critical value cause permanent rapid flow The smaller the applied pressure difference the smaller is the volume passed before the limiting slow flow is reached and after attainment of this limiting flow in one direction immediate reversal of the pressure difference (keeping its magnitude the same) simply reverses the flow at the limiting value the initial rapid stage being eliminated

Crystal Structure of Succinic Acid

The cell dimensions of the low temperature form of succinic acid have been found to be $a = 5$ 10 $b = 8$ 88, $c = 7$ 61 A $\beta = 133°$ 37 , in agreement with those found by Yardley[1] with other choice of c axis—and Dupré la Tour[2] The space group is $C_{2h}^5 - P2_1/a$ The cell contains two molecules , as the general atomic position of the space group $P2_1/a$ is 4, this leads to the conclusion that the molecule has a centre of symmetry

The crystal shows pronounced fibre cleavage along the c axis, this being also the direction of the largest refraction index These facts indicate that the molecule lies along the c axis the length of which 7 61 A is in accordance with this assumption To find the azimuth round this axis a Patterson analysis of the [001] projection was made this shows a relatively narrow ridge going through the origin and making an angle of about 37° with the b axis This ridge will correspond to inter atomic distances in the molecule which is accordingly approximately flat, lying in a plane through the c axis and intersecting the a b plane along the direction shown by the ridge A second hump of greater dimensions in the middle of the projection can be interpreted as caused by the inter molecular distances As the details of the Patterson analysis were not very clear owing to many distances overlapping it was not possible to derive further information from it

Several models were found to be possible on geo metric grounds Only one of these models gave reasonable agreement with the intensities of the reflections *hkO* *hOl* and *Okl* On the basis of this model Fourier analyses of the projections [100] and [010] were made The resulting parameters are

	x	*y*	*z*
C_1	0 021	0 036	0 258
C_2	0 056	0 067	0 081
O_1	− 0 133	−0 080	0 253
O_2	0 167	0 142	0 422

The distances between the C atoms were found to be 1 52 and 1 51 A in accordance with the standard distance 1 54 A for the single aliphatic bond In this respect, succinic acid differs strikingly from oxalic acid where the C C bond is found to be considerably shortened by the influence of the carboxyl group[3] The C C bonds include an angle of about 110°

The calculated C O distances are 1 28 and 1 31 A O O in the same molecule is 2 28 A the distance between oxygen atoms of different molecules is 2 65 A

The details of the structure and of its determina tion will be published elsewhere

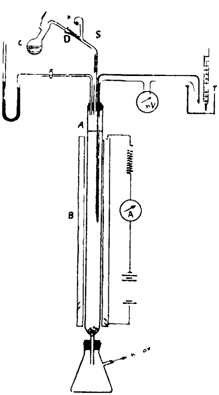
A New Method of Resolving a Racemic Compound

WE have recently developed a new method of resolving a racemic compound by selective adsorption and the results we have obtained already published in the *Praktika* of the Academy of Athens (April 1938) agree in the main with similar experiments of G M Henderson and Dr H Gordon Rule[1]

The method is based upon the different degree of adsorption which an optically asymmetric crystal as *d* or *l* quartz shows, for the two antipodes The result of this selective adsorption is that when a *d l* solution is passed through a Tswett column its *d* and *l* components are separated and located at different heights.

We used quartz powder prepared from *d* and *l* quartz crystals as the asymmetric adsorbing medium and a solution of tri ethylenediamine chromichloride ((Cr en_3) Cl_3 + 3½ H_2O) as the racemic compound We have chosen this compound because of its great molecular rotation power which is 3 000° for 5890 *A*

The apparatus employed is shown in the figure below After activating the adsorbing medium by heating in vacuum we let the racemic solution pass through the column *A* of the quartz powder by breaking the glass end S by the metal sphere *K* and tipping up the vessel *C* thus avoiding contact with any grease



Then we examined the filtrate in the polarimeter and the solutions obtained by successive elutions of the adsorbed salt by 85 per cent alcohol As the accompanying table indicates, the solutions obtained show optical activity By using *d* quartz the first elutions are dextro rotatory and the next solutions are lævo rotatory By using *l* quartz the opposite occurs This indicates that the asymmetric quartz surface adsorbs more strongly the antipode of the opposite sign

OPTICAL ACTIVITY OF SUCCESSIVE ELUTED SOLUTIONS

Adsorbing medium	I	II	III	IV	V
l quartz	0 023	0 041	0 020	0 108	
l quartz	0 058	0 121	0 018	0 046	+0 034
d quartz	+0 023	0 020	0 0[illegible]0		

It is easily shown by a thermodynamic cycle that the selective adsorption of the antipodes by optically asymmetric surfaces can be reduced to a difference in the heat of formation of the adsorbed antipode molecule from adsorbed atoms on the asymmetrical quartz

These experiments throw a new light on the problem of the genesis of the first substance with optical activity It is possible that this substance was formed by many successive adsorptions and elutions of a racemic compound on optically asymmetric surfaces of minerals

Experiments are in progress with the object of extending the research to other substances the details of which will be published elsewhere

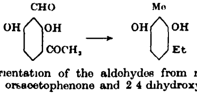
Modified Gattermann Reaction Synthesis of Hydroxy-Formyl-Phenyl-Ketones

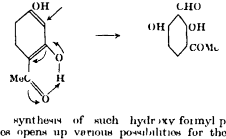
ONE of the authors (R C S) with Laiwalla has previously shown that methyl β resorsylate does not undergo the Gattermann reaction under the usual conditions, that is, in the presence of zinc chloride in ether or in the presence of aluminium chloride in benzene , the reaction takes place readily, however in the presence of anhydrous aluminium chloride dissolved in dry ether, with the formation of the aldehydo ester, methyl 2 4 dihydroxy 3 formyl benzoate[1]

We now find that polyhydroxy phenolic ketones also give aldehydes in high yields under the condition of Shah and Laiwalla s modified Gattermann reaction[1] the formyl group entering (when possible) the usually inaccessible *Y* position in the resorcinol nucleus Thus resacetophenone gives 2 4 dihydroxy 3 formyl acetophenone, the constitution of which is established by its reduction by the Clemmensen method to 4 ethyl 2 methyl resorcinol of Robinson and Shah[2]

Orsacetophenone, 2 acetyl resorcinol, 2 4 dihydroxy benzophenone and phloracetophenone afford similarly 2 4 dihydroxy 6 methyl 3 formyl acetophenone, 2 6 dihydroxy 5 formyl acetophenone, 2 4 dihydroxy 3 formyl benzophenone and 2 4 6 trihydroxy 3 formyl acetophenone respectively



The orientation of the aldehydes from resacetophenone, orsacetophenone and 2 4 dihydroxy benzophenone in which the formyl group enters the 3 position instead of the usual 5 position is of interest These results are best explained on the view that the chelation between the hydroxyl and the acetyl group stabilizes the double bonds in the resorcinol nucleus , the carbon atom in the 3 position which is united by a double bond to the carbon atom bearing the 4 hydroxyl group is thus the point of attack (*cf* W Baker[3])



The synthesis of such hydroxy formyl phenyl ketones opens up various possibilities for the synthesis of heterocyclic compounds containing oxygen in the ring like coumarino *Y* pyrones furo chromones etc which are being explored

A detailed account of the above investigation will shortly be submitted to the Chemical Society

Long-distance Radio Reception and the E-Region of the Ionosphere

MR ALEXANDER A McKENZIE of the Mount Washington Observatory has reported a well marked case of the long distance reception of amateur 56 60 megacycle signals which occurs occasionally at this time of year A letter from him reads in part We started listening about 1930 E S T (June 5 1938) and listened continuously until about 2045 During the whole time long distance signals were fading in and out fairly rapidly with extremely audible volume at the start for instance of a call letter group and absolute silence before the group was completed

Mr McKenzie, on Mount Washington, heard twelve Middle Western stations, and reports a supplementary list of seven other stations which were being called by various amateur stations in the New England area With two exceptions which may be ascribed to faulty identification the stations heard in New England appear to have been closely grouped about a point somewhat south of Chicago The minimum and maximum distances involved are 780 and 960 miles the mean being 880 miles

Continuous records of the heights of reflections from the ionosphere are made at Cruft Laboratory at a frequency of 3 5 megacycles On the night in question, remarkably strong abnormal *E* region reflections were observed from 1912 to 2035 E S T , the number of multiple reflections varying from four to six At 2035 the reflection began to decrease in intensity, and it disappeared completely at 2050. The apparent height of reflection was 120 ± 3 km. throughout the period

We may identify the long distance transmissions as being caused by extremely high ionization in the *E* region and, from the observed height and distance, deduce a minimum ionization density which must have obtained on this occasion The angle of incidence of the transmitted rays upon the *E* layer was such that the critical frequency for normal incidence must have been slightly more than one fourth of the transmission frequency, or about 15 megacycles This corresponds to a density of free electrons of about 2 8 $\times 10^6$ per cm^3, or their equivalent in heavy ions Too little is known of the effective recombination coefficients at such heights to permit the calculation of the corresponding energy density On the assumption, however, that the highest frequency normally reflected from the *E* region is about four megacycles we may say that the ionization producing energy on this occasion was about 200 times that due to ultra violet light at noon on a summer day

Enhancement of the Sodium *D* Lines in the Twilight Sky Light

Prof J Cabannes, Prof J Dufay and J Gauzit[1] state that the twilight enhancement of the yellow radiation of the night sky announced by me[2] was previously observed by Currie and Edwards at Chesterfield (Canada) during the International Polar Year, 1932 33 To support their opinion, they give a short quotation from a paper published in 1936 by the Canadian physicists[3] The complete sentence should have been quoted , it is as follows

The fairly uniform intensity of 5940 during moon light irrespective of the intensities of the green line and the negative bands, indicates that it is due to a luminescence distinct from that of the aurora and is probably the radiation 5893 A observed by Vegard and Tonsberg in the night sky light

Thus the band around 5940 A appeared to Currie and Edwards remarkably constant during the moon light periods It is only upon this observation that they based their suggestion However, if it is quite certain that the band at 5940 does not belong to the auroral spectrum, it is no less certain on account of its aspect and evolution, that it cannot be identified with the sky line 5893 A Currie and Edwards also state "It appeared to be a broad, diffuse band extending from about 6000 A to 5800 A with a mean wave length of 5940 A This broad and diffuse appearance (200 A) cannot be that of an atomic line or narrow doublet On the contrary, it can be explained very exactly by the spectral sensitivity of the plates (Ilford Soft Gradation), which offer a sharp and strong maximum exactly in this region, and by admitting that the so called band near 5940 A originates from the continuous spectrum of the moonlight In fact, the intense yellow band obtained by Currie and Edwards remains absolutely invisible when the auroral spectrum is photographed, with full moon, on another type of plate (Agfa I S S) Taking into account some supplementary arguments, developed in another paper[4], it seems beyond doubt that the yellow sky radiation 5893 A was never observed by Currie and Edwards It is thus clear that their work gave me no information or suggestion likely to guide me in the discovery of the yellow fluorescence or resonance of the twilight sky

Use of Non-Conservative Properties of Sea Water to Physical Oceanographical Problems*

IN applying the eddy diffusion equation to the non conservative properties of sea water (as distinguished from the conservative properties, the concentrations of which change only as a result of physical processes) a knowledge of the time rates of change in their concentrations (as a result of the biological activity in the water mass) is required Thus, the form of the equation expressing the effect of vertical turbulence alone on a non conservative property, such as oxygen would be

$$\frac{d\alpha}{dt} \quad A \frac{\partial^2 \alpha}{\partial t^2} - C,$$

where, for dissolved oxygen α the term C would represent the rate of oxygen consumption due to the biological activity in the water mass The consumption of oxygen in the sea as a means of disguising the oxygen transport by turbulence is frequently strikingly brought out at the depths of the oxygen minimum concentration where regardless of enrichment by eddy diffusion oxygen concentration actually decreases in the downstream direction due to the greater rate of oxygen consumption

Information on the rate of oxygen consumption in the depths of the ocean basins is confined chiefly to results obtained for the mid Atlantic between latitudes 0° and 30° N , where the mean annual oxygen consumption at mid depths was placed at approximately 0 42 c c per litre and that in the deeper water at approximately 0 10 c c per litre Use has been made of the former value in calculating the magnitude of the vertical eddy coefficient at mid depths (at depth of the minimum oxygen concentration) in the Caribbean basin , where, with certain assumptions, the gain and loss of oxygen in the downstream direction could be formulated, thus

$$Ct = O_1 - O_2 + A \frac{\partial^2 O}{\partial t^2} t$$

where Ct represents the amount of oxygen consumed in the downstream direction by biological activity as the water layer (at the depth of the minimum oxygen concentration) moved, during the time, t, from position 1 to position 2 , $A \frac{\partial^2 O}{\partial t^2} t$, the amount of dissolved oxygen gained as a result of vertical turbulence during the same time (effects due to lateral turbulence are neglected) , and $O_1 - O_2$, the observed difference in oxygen concentration (at the depth of the minimum oxygen concentration) between positions 1 and 2 The combination of this equation with a similar one involving the conservative property (salinity) at adjacent depths gave two equations which were solved simultaneously for the values of *A* and *t*.

---

* Contribution No 181 from the Woods Hole Oceanographic Institution

Substances dissolved in sea water the concentrations of which are altered by biological activity are useful in investigations of its circulation when used either as simple identifying properties or in combination with a conservative property; in such cases it is frequently not necessary to know the rate of the biochemical change of concentration. Particularly useful combinations of conservative and non-conservative properties, such as oxygen and salinity, or oxygen and temperature, may under certain defined conditions be used to trace movements and mixing of water masses and to supplement the results of circulation as calculated from the Bjerknes circulation theorem. The oxygen-salinity or oxygen-temperature relationship has its counterpart in the temperature-salinity relationship (originated by Helland-Hansen), but differs in that the latter strictly conservative relationship is chiefly useful in interpreting combinations of water masses of distinctly different physical properties, whereas the combination of conservative and non-conservative properties may be used advantageously in investigating characteristics of a water mass of marked homogeneity. The latter relationship recently used in an investigation of the water (between approximate depths of 200 and 1,200 metres) in the Caribbean Sea region made it possible to trace the movements and mixing of water masses entering the passages from the open Atlantic and to bring out certain details not clearly indicated by the temperature-salinity relationship.

Effect of Addition of Calcium on the Biological Value of the Proteins of Indian Diets

During our investigations[1] on the biological value of the proteins of typical Indian diets, it was found that the proteins of the Madras diet gave a biological value of 44 at 10 per cent protein level, though rice with a biological value of about 83 formed the major item of the diet. In the course of an informal discussion with Dr. W. R. Aykroyd, director of the Nutrition Laboratories, Coonoor, he suggested that the low biological value might be due to a low content of calcium in the diet. Experiments were conducted with addition of calcium in the form of calcium carbonate to the Madras diet. Results are given below.

CALCIUM IN DIET 0·124 PER CENT

Rat No.	Initial weight (gm.)	Final weight (gm.)	Digestibility (%)	Biological value (%)	Average
1	130	134	59	34	44
2	115	123	65	45	
3	165	169	61	45	
4	123	130	64	44	
5	114	119	66	45	
6	94	103	69	52	

CALCIUM IN DIET 0·124 PER CENT + 2 PER CENT CALCIUM CARBONATE

Rat No.	Initial weight (gm.)	Final weight (gm.)	Digestibility (%)	Biological value (%)	Average
1	105	109	86	66	76
2	102	107	93	81	
3	109	125	85	71	
4	105	114	87	81	
5	94	99	90	79	
6	122	130	92	78	

Examination of the above results reveals that the biological value of the proteins of the Madras diet increases from 44 to 76, and the digestibility from 64 to 89 on the addition of calcium to the diet, even though the calcium content in the Madras diet is just enough according to Sherman's accepted standard for an adequate diet. The low biological value in the first table might be due to the non-availability of calcium in the diet. Further work to confirm the above observation is in progress.

Biological Fixation of Nitrogen

The oxime which is formed in the root nodules during the nitrogen fixation of legume bacteria[1] has at last been isolated and characterized. The oxime precipitates according to Foreman's method, which fact already indicates it to be the oxime of a dicarbonic acid. Extracting the oxime with ether, we succeeded in preparing the copper salt from it. The analysis of this salt showed that the compound is the oxime of oxalacetic acid. Thus the formation of aspartic acid in the biological fixation of nitrogen via the oxime of oxalacetic acid has been finally confirmed.

Electric Lines of Force

When a piece of cotton wool is placed on one of the charged spheres of a Wimshurst machine, it is immediately repelled and following the lines of force in the air, proceeds to the oppositely charged sphere. This is the usual method of demonstrating the phenomenon, but it is not always easily controlled.

I have recently been trying substitutes for the cotton wool, amongst them the down of birds. The down was furnished by my budgerigar. I find that the down attached to the base of the feathers which the bird pulls out answers the purpose admirably. A piece of this placed on a charged sphere, gradually takes up the charge, the fine points of the immature feather standing out, and finally leaps across the four or five inches of air separating the two charged spheres. If the spheres are not highly charged it may be as long as five seconds or so before the repulsion takes place.

The way the charge is taken up is extremely interesting and worth projecting on a screen. The down is a poor conductor with many fine points. I think this explains its peculiar behaviour.

The electric lines of force are well shown by this method as it is possible to have two or three pieces of down going to and fro at the same time.

Points from Foregoing Letters

FROM the rate of sedimentation (in an ultracentrifuge) of the serum proteins of various vertebrate animals Prof The Svedberg and K Andersson infer that the serum proteins of mammals reptiles birds amphibians and fishes are very much alike as regards molecular weight but differ from those present in the serum of Cyclostomata (lampreys)

A new dye dunnione found as a deposit on leaves and flowers of *Streptocarpus Dunnii* is described by J R Price and Prof R Robinson It crystallizes in orange red needles has the molecular formula $C_{15}H_{14}O_3$ and belongs to the naphthalene group

The copper found in human blood occurs in the form of a copper protein compound according to Dr T Mann and Prof D Keilin who announce that they have isolated from the red blood corpuscles of the ox a pure crystalline compound (hæmocuprein) containing 1 12 per cent sulphur and 0 34 per cent copper

A new hybrid hæmoglobin (choleglobin) formed by special treatment of hæmoglobin ascorbic acid solution is described by Dr R Lemberg J W Legge and W H Lockwood The new compound like hæmoglobin combines reversibly with oxygen and carbon monoxide but the non protein part of its molecule is a bile pigment closely related to verdohæmatin

H S Corran and Dr D E Green describe the isolation from cow s milk of a flavin protein compound which catalyses the oxidation of reduced coenzyme I by carriers The mechanism of the catalysis does not seem to involve alternate reduction and oxidation of the flavin moiety

A new enzyme which hydrolyses naringin the bitter glycosidic principle of grape fruit may be readily obtained from celery according to Dr D H Hall It also occurs in the grape fruit itself between the flavedo and albedo where it probably helps to reduce the bitterness of the fruit on ripening

Dr H G K Westenbrink and Dr J Goudsmit have determined by a modified thiochrome method the relative amounts of the two forms of vitamin B_1 (aneurin and cocarboxylase) in various organs of the rat and find that the aneurin content is small compared with carboxylase

Dr J H Welsh states that the acetylcholine found in the nervous tissue of the crab has upon the heart of that animal an effect opposite to that upon the human heart namely it increases the rate of beat

T L Snyder and R H Broh Kahn find that cysteine can replace hæmin as the X factor enabling *H influenzæ* to grow and consider that its function is to provide the organism with a mechanism for protection against the hydrogen peroxide formed in the presence of air

Diagrams showing the average density of population and the composition of the insect fauna at heights of 277 ft 177 ft and 10 ft above an area of agricultural land in Lincolnshire is submitted by J A Freeman The greatest numbers and variety occurred during the months of June and September and the most favourable conditions were high temperature, low humidity and wind velocity A list of the more common pest species taken up to 277 ft is given and the economic importance of their presence is discussed with reference to ground quarantines

Dr R W G Dennis observes that the potato virus Y induces brown circular local lesions in the leaves of *Lycium barbarum* seedlings and suggests that this reaction may prove of value as a new test for the Y virus

For several years Dr T Burrow and his associates of the Lifwynn Foundation have been experimenting with differences in physiological reaction according (1) as behaviour is motivated naturally by the organism as a whole or (2) as it is prompted by secondary part components giving rise to neurotic phantasies and related behaviour disorders

Diagrams of chromosomes from the root tip cells of the saffron during mitosis are submitted by Prof R R Gates and G N Pathak in which the double structure of the chromosomes is rendered evident by the presence of satellites The authors state that by means of a new method which stains the chromatin red and the nucleolar material green the origin of the nucleolus from the split chromosomes can readily be followed

Curt Stern states that he has shown by means of transplantations of testes between two species of *Drosophila* that the distinguishing characteristics in testicular shape are induced by a difference in the male ducts

The non ionizing penetrating radiation producing cosmic ray secondaries and showers is considered by N Arley and Dr W Heitler to be a neutral body corresponding to the heavy electron The authors suggest for a new entity which has a mass intermediate between the neutron and the neutrino the name neutretto and discuss its likely properties in the light of present theories

Prof H R Robinson points out that when the most recent values of the coefficient of viscosity of air are used Millikan s oil drop value of the electronic charge comes into almost exact agreement with the X ray value namely 4 803 × 10^{10} E S U

Starting with the solution for the electron velocity ripple in terms of the transit half angle W E Benham points out that the ripple satisfies a five dimensional wave equation

Dr U R Evans describes a treatment which renders iron relatively inert to ordinary waters the time taken to produce rustiness being sometimes 100 times that needed by untreated iron in the same water The protective film is invisible and the engraving of a scratch line after treatment does not necessarily lead to rusting probably because it presses down the film into the groove

Solutions of the copper salt of cetyl phenyl ether sulphonic acid and other salts of the newer paraffin chain series show elastic behaviour similar to that of ammonium oleate solution when they are set in motion According to Dr G S Hartley this is the opposite of thixotropic behaviour and has been explained by Hatschek as due to the formation of amicroscopic structure by the process of shear

H A and Dr R C Shah have formulated polyhydroxy phenols by a modified Gattermann reaction The 3 substitution is explicable on the assumption of the stabilization of the double bonds in the nucleus by the chelation between the hydroxyl and the acetyl groups

40° N., following a course New York Paris Moscow — Omsk — Yakutsk (Siberia) — Fairbanks (Alaska)—Minneapolis—New York. They covered a distance of 14,874 miles in 3 days 19 hours 17 minutes. Their actual flying time was 71 hours 4 minutes at an average speed of 209 miles an hour. They followed a somewhat similar route to that taken by the late Wiley Post, the American aviator, who established a record of 7 days 18 hours 49 minutes for a flight of 15,250 miles in 1933. Their machine was a Lockheed 14 monoplane powered by two 875 horse power Wright Cyclone engines with Hamilton constant speed airscrews. Normally this type is a 14 seater air liner carrying 12 passengers and 2 crew. While this is a meritorious performance having been completed in only seven stages it is not a record for long distance non stop flight. The longest hop was New York Paris, a distance of 3 641 miles.

SUCH a performance pays tribute principally to the technical improvements that have added to the reliability of the engines and the rapid strides that have been made recently in the methods of and aids to, aerial navigation. It is significant of the development of this side of aviation that even in the less developed parts of Siberia there were sufficient aerodromes and radio organization to allow of a choice of landing grounds after being given reports upon their condition while flying towards them. The extra carrying capacity consequent upon developments in aerodynamic knowledge plays its part in allowing various aids to flying and navigating to be carried, and also making it possible to have cabin accommodation sufficiently large for the crew to move about and to carry out their duties without undue strain. In one instance, in Siberia during this flight it is reported that they even had room to carry an extra supply of more than 500 lb. of oil, as it was reported that the particular grade that the engines needed would not be available at the next stop. It is interesting to note that the engines used on this flight are of the same type as those fitted to the Lockheed aircraft recently ordered by the British Government.

'Aryans' in Italy

NATIONALIST doctrine in Italy hitherto has had the appearance of avoiding pronouncement upon theories of race. It has relied rather on fostering the totalitarian spirit upon imperial tradition with a consequent orientation to archæological research for which the learned world is duly grateful to the personal interest of the Duce. Now, however it is said to be time that the Italians frankly professed themselves to be racist. A group of university professors, it is reported (*The Times*, July 15) working under the auspices of the Ministry of Popular Culture, has drawn up a pronouncement appearing in the *Giornale d'Italia* of July 14, in which is stated what is to be regarded henceforth as the orthodox view of racial doctrine as applied to Italy. This statement has the merit that it recognizes that the idea of race is a purely biological concept, with which history language and religion have nothing to do. It claims that the present population of Italy is in its majority Aryan few elements of the pre Aryan races remaining and no immigration of populations capable of influencing the racial physiognomy of the nation having taken place since the Lombardic invasion. The forty four million of inhabitants of Italy to-day it is maintained are for the most part descended from families which have been established there for at least a thousand years. While this may be conceded but only so far as it goes the inference that the Italian race—a term which in itself begs the question can thus be regarded as a pure race is perhaps less readily to be accepted. The corollary that racism in Italy ought to be essentially Italian with an Aryan Nordic direction is a hard saying, only partially intelligible, especially in view of the repudiation of linguistic evidence in the light of the evident desire to dissociate the Italians from other members of the Mediterranean racial group by emphasizing its purely European characteristics as marking it off from all extra European races. This view would ignore or deny any trace of kinship between the Mediterranean strain in the Italian and that in the peoples of North Africa Arabia, and Palestine. This would seem to require a somewhat drastic re interpretation of the facts.

The Deutsche Orient-Gesellschaft

A NOTICE from the Deutsche Orient Gesellschaft, of which the following is a translation, has reached its members, including British subjects and honorary members. To the Members of the German Orient Society. To ensure the continuance of the German Orient Society, the Executive Committee must, in accordance with Paragraph 8 Section d of the Constitution give those members who rank as Jews in the sense of the Nuremberg Laws to understand that they must announce their resignation from the German Orient Society within 14 days.' The notice is signed by Dr. F. Schmidt Ott (vice president) and Dr. W. Andrae (secretary) of the Society. Though the Society has been compelled by the policy of the Government to take this step of asking Jews to resign, the wording of the announcement is altogether unworthy of a scientific body and is particularly unpardonable when sent to members who are not Germans.

THE Deutsche Orient Gesellschaft was formed in 1898, mainly under the inspiration of Prof. Friedrich Delitzsch, a Jew in the sense of the Nuremberg laws. The main aims of the Society were to excavate ancient sites and survey ancient monuments in the Near East and Egypt. Three great sites in Iraq have been carefully examined over a long series of years—Babylon, Ashur and Uruk—and many other smaller sites sounded. In Egypt, excellent work was done at el Amarna and on the sepulchral monument of Sahu Re. Surveys of Ukhaidhir, the ancient synagogues of Palestine and Islamic monuments in India were perhaps the most important contribution to these subjects. Regular "Mitteilungen" kept subscribers informed of progress. Final reports, and most important publications of the texts found were included in the "Wissenschaftliche Veröffentlichungen" These undertakings were generously supported in Germany by such men as the late Dr. Simon, and foreign subscribers were numerous For forty years the Deutsche Orient Gesellschaft has held a leading place among societies of its kind, always insisting on a high standard of work in the field and the study not always attained by others Sir Robert Mond was one of the foreign members who received the letter asking for his resignation and he informs us that he has answered, "that since your Council has unanimously decided to cease to be a scientific society, he no longer desires to be associated with it"

Archæological Exploration in South-West Arabia

In another column of this issue of Nature (see p 140) a preliminary account is given by Miss G Caton-Thompson of the geological and archæological results of the Lord Wakefield Expedition of Exploration in South-West Arabia, upon which she recently accompanied Miss E W Gardner, the geologist, and Miss Freya Stark, whose adventurous journeying in Arabia on a previous occasion will be fresh in the memory of readers. Miss Caton-Thompson, whose present record amplifies in detail the archæological and geological references of Miss Stark's account of the expedition in *The Times* of July 18–21, is far from being a novice in archæological exploration in conditions similar to those of her recent experience With Miss Gardner as her geological colleague, she has investigated the evidences of early civilizations in the Faiyum and the Kharga oasis, while in Southern Rhodesia she has attacked, and, most archæologists would agree, has solved the problem of the Zimbabwe In venturing with her colleagues into the rarely penetrated Hadhramaut she has initiated the archæological investigation of a problem, or group of problems, which has fascinated historian and geographer ever since the explorations in southern Arabia of Niebuhr in 1761–64 and of Halévy and Glaser more than a century later revealed in their collection of inscriptions the existence there of civilizations going back possibly so far as nearly a thousand years before Christ Yet the archæological record has remained virtually blank, and although the great frankincense route from India to the eastern Mediterranean through southern Arabia traversed country known to the ancient world of Sumer, Akkad and ancient Egypt, it may be, in the third millennium B C , nothing is known with certainty of the cultures and relations of those civilizations. Minaean, Sabaean, Himyaritic, and the like, which Miss Caton-Thompson, wisely, for the moment accepts collectively as pre-Islamic. The work of Miss Gardner and herself in the Hadhramaut has laid securely the foundations for the study of a group of problems which recent development in the pre- and protohistoric archæology of western Asia and Africa suggests may be one of the most important strategic points in future research.

Excavations at Lachish, 1937-8

The interesting collection of antiquities from Tell Duweir, the ancient Lachish, in Palestine, on view at the Wellcome Research Institute, Euston Road, London, N.W 1, from July 7 until July 29 bears eloquent testimony to the organization of detail by the leader of the expedition, the late Mr J. L Starkey, which enabled the members of the Wellcome-Marston Archæological Research Expedition to carry on without interruption after his murder on January 10 last By that time the expedition had already arrived as near a solution as is likely to be possible of the problem of the great shaft, 80 ft by 70 ft by 80 ft deep, at the south east corner of the Tell upon which investigation was engaged at the close of last season. Tunnels driven along the sides at the bottom and up to the centre show that this great seventh century work was never completed, but that it was probably intended for a reservoir similar to that at Gezer Excavation of the Bronze Age temple has now been completed down to bed rock, two pieces of evidence leading to redatings.

The early temple is now shown to be considerably earlier than was believed, a remarkable large polychrome pot with painted metopes, showing beautiful representations of ibex, ibis and tunny fish, being placed in a class of pottery dated by Mr W A. Heurtley at about 1550 B C ; while a small faience plaque of Amenhotep III was found in such a position as to place it beyond question that the building of the second temple falls within the reign of that monarch. Two Nineteenth Dynasty pottery sarcophagi, the first found at Lachish, in the form of 'slipper' coffins, have lids moulded to represent the features of the deceased, while a third bears an inscription in hieroglyph which is unique. It is by a scribe evidently unfamiliar with hieroglyphic writing, and although not yet fully interpreted, is in a formula which is not Egyptian Early Bronze Age caves, dating at about 2500 B C , showed evidence of occupation, as well as contracted burials In one cave, of the Late Bronze Age, which in Judæan times had been used as a stable, was found a number of unfired pots which pointed to this having been a potter's workshop, while nearby in another cave was his stock in trade In a pit were pivoted stones which may have served as fly-wheels for the turn-table, while red and yellow ochre for painting, bowls for mixing the paints, pebbles and shells for polishing and burnishing, were part of the equipment. The interesting schoolboy scribing giving the order of the first four letters of the Judæo-Phenician script was found under the Jewish Palace steps the day the expedition ceased work.

Archæological Research in Greece

Among recent excavations and research in Greece recorded in the Annual of the British School of Archæology at Athens (35, Session 1934–35), first place in interest and importance is taken by the work of the School in Ithaca. Mr. W. A. Heurtley, who was in charge, describes the results of the excavation of the Helladic settlement at Pelikáta, which Leake and others have identified with the home of Odysseus as described by Homer. Pelikáta is a hill or spur linked on one side with the central peak of the island, and sloping down to the sea in a series of terraces on its three other sides. Thus commanding three bays, and having a flat top, it was, as Mr Heurtley points out, an admirable site for a primitive community interested in trade or piracy or both. Virtually no trace of buildings remained when investigation began, but there were vestiges of the wall which had enclosed the promontory. Excavations on the site yielded evidence of an early Helladic settlement, which on the evidence of the pottery, Mr Heurtley concludes, reached the island in Early Helladic II from Corinthia, and afterwards received an accession in a new element in the population, which Minyan ware indicates to have come from the south of Thessaly as its immediate place of origin, with an ultimate derivation from Bronze Age Macedonia.

THE date of the original occupation of Pelikáta is placed at about 2200 B C, the settlement then being a simple affair—a wall of rough stone blocks surrounding a group of houses with rubble walls and roofs of reeds daubed with mud situated on top of the hill. These people buried their dead, or rather the bones of their dead in *pithoi* or jars which, possibly, were placed below the floors of the houses. The settlement came to an end at about the time which tradition assigns to the Trojan wars, and thus, Mr Heurtley remarks, those who hold on other grounds that Pelikáta is to be identified as the site of the palace of Odysseus now have some archæological evidence to support their contention. A cave containing stratified deposits on the north east of the bay of Polis was excavated by Miss Sylvia Benton and showed evidence of occupation from pre Mycenæan times to the first century A D. It was a shrine at which various deities were worshipped, but its local importance seems to have been due to a connexion with Odysseus, for which there is evidence in an inscription on a female mask.

Garden Plants of Proved Excellence

THE Council of the Royal Horticultural Society established, in 1922, an Award of Garden Merit as a hall mark upon the horticultural worth, hardiness and beauty of particular plants. Notes and descriptions of species which have attained to this particular quality have been published from time to time in the Society's *Journal*, but it was a welcome decision of the Council to publish the collected awards during the past fifteen years in a separate volume ("Some Good Garden Plants", by F J Chittenden. London from the Society's Offices, Vincent Square S W 1 1938 4*s* net) The plants described therein have mostly been grown in the Royal Horticultural Society's gardens at Wisley, and are all well known to the Garden Committee. A horticultural description, cultural notes, and suggestions for suitable garden grouping, are appended for each of the 225 species or varieties, and the most suitable soil types are mentioned. References are also given to plates in the *Botanical Magazine*, when the plant has been so figured. Some kinds, as *Lilium regale*, *Dicentra spectabilis*, *Primula denticulata*, *Daphne mezereum* and *Clematis montana* are already well established in favour, other species have recently been introduced to culture from plant collecting expeditions, whilst yet others are improvements of very common plants. *Ulex europaeus flore pleno* is a double variety of the common gorse, *Caltha palustris plena* is a dignified form of the wild marsh marigold, and three improved varieties of the common lilac are described. An alphabetical arrangement assists quick reference, whilst an index divided into annuals, bulbous plants, herbaceous perennials, rock plants, shrubs, small trees, wall and climbing plants and water plants enables the gardener to find his way easily among these aristocrats of the garden.

Child Psychology for Parents

WE have received a copy of an address delivered recently to the parents' association of a school well known for its pioneer work in the field of organized practical training for citizenship. The address is noteworthy if only as a too rare example of effort towards parent teacher co operation. The author, Dr Oswald Schwarz, sought to demonstrate what he described as one of the greatest discoveries of modern psychology—that the foundations of happiness in later life as well as of all troubles, difficulties, problems and abnormalities, are almost invariably laid in the first few years of our childhood. The only real problem in education is, he holds, the problem of an aim in life and its solution is to be sought in evoking and fostering an attitude of respect, or 'the appreciation of the inherent value of everything existing just because it exists'. He shares, apparently, with Whitehead the notion of actuality as in its essence a process, involving, on the mental side a weaving of reception and anticipation into an end to which its indwelling Eros urges the soul as to the realization of ideal perfection. To the objection that such philosophical ideas do not work with children he answers that he knows from fairly wide personal experience that most boys from the age of sixteen years onwards are not only able to conceive these ideas but that they grasp them eagerly as if they had long waited for them", which accords with Whitehead's "youth is peculiarly liable to the vision of that Peace which is the harmony of the soul's activities with ideal aims that lie beyond any personal satisfaction.

The Brotherton Collection of the University of Leeds

THE second annual report of the Brotherton Collection Committee refers to the considerable interest in the Brotherton Collection which is available for the use of the University of Leeds staff, students, research scholars and the public. The numerous exhibitions which have been arranged, including technical exhibitions for the Process Block makers' Society, Printers' Guild, the Technical Institute, and the Society of Chemical Industry, have attracted some 2,300 visitors. Detail work such as lighting and heating adjustments, painting and additional fittings which was incomplete at the opening of the Library in October 1936, was completed by the end of the Easter vacation Good progress was made with the catalogue and cross reference index The income of the Library is limited to about £1,250 per annum and the accounts show a balance in hand of £96 8s Particulars of gifts and additions during the year and of the regulations governing access to the Collection are included

British Scientific and Technical Books

THE second edition of the Select List of Standard British Scientific and Technical Books has been prepared by the Association of Special Libraries and Information Bureaux, at the request of the British Council (ASLIB, 31 Museum Street, London, W C 1 Price 2s to Book List Subscribers, 2s 6d to others 1s to members of ASLIB or the Library Association) In the preparation of the list, the Book List Committee consulted authorities upon every subject, so that the books may be justly regarded as representative of existing works in science and technology now available from British publishers About three hundred books are included in the list, which is subdivided into twenty three sections Sections on agriculture and on medicine and surgery have been added in the revised edition A list of publisher's addresses and a subject index are appended

Beit Fellowships for Scientific Research

THE following Beit fellowships for scientific research tenable at the Imperial College of Science and Technology during the Academic Year 1938 39, have recently been awarded extensions of fellowships already satisfactorily held for one year to D W Goodall, for research on the physiology of the tomato plant, under the direction of Prof F G Gregory, H A C McKay, for investigations of chemical problems by the radioactive indicator method, under the direction of Prof H V A Briscoe, A K Powell, for research on parasitic wasps, in particular that of *Microbracon hebetor*, under the direction of Prof J W Munro New fellowships tenable for one year but renewable for a second have been awarded to J L O G Michiels (Royal College of Science), for research on the positions and widths of the energy levels of atomic nuclei by means of experiments on the capture of slow neutrons by various elements, under the direction of Prof G P Thomson, E J Harris (Royal College of Science), for research on hydrocarbon oxidation and the reactions of peroxides with reference to carbon processes, under the direction of Prof A C G Egerton

Announcements

DR MONTAGU TRAVERS MORGAN, medical officer of the Ministry of Health, has recently been appointed medical officer of health of the Port of London by the London Corporation

AN exhibition dealing with the prevention of industrial eye diseases was opened at the Royal Eye Hospital, London, on June 22 by the Earl of Athlone Part of the exhibition is to remain in the hospital as a permanent museum

AN intensive course in industrial hygiene and medicine will be held at the University of Birmingham on September 12 23 Further information can be obtained from Dr H E Collier Department of Industrial Hygiene and Medicine The University, Birmingham

THE Minister of Justice in Portugal has transformed the Department of Criminal Anthropology, Experimental Psychology and Civil Identification into an Institute of Criminology on modern and strictly scientific lines under the direction of Dr Luiz de Piña

A CONFERENCE on Plant and Animal Communities will be held at the Biological Laboratory Cold Spring Harbor Long Island, New York on August 29 September 2 Three general papers will be read and six will be read on association concepts and four on animal aggregations These will be followed by discussion the whole of which will eventually be published in the *American Midland Naturalist* (**20**, No 1, January 1939) Further information can be obtained from the Director of the Laboratory

THERE has recently come to hand No 1 of vol 8 of the *Bulletin of the Fan Memorial Institute of Biology*, Zoological Series This journal is published by the Institute at Peiping (Peking) and the present issue bears the date March April, 1938 It is gratifying to note that notwithstanding the present disturbed conditions in China, it is possible for scientific work to be carried out The present number covers a variety of zoological subjects and the contributions are written in the English language by Chinese investigators, each article being accompanied by short Chinese abstracts The illustrations are well reproduced and of a high standard

FROM the Nottingham University College Appointments Board we have received an attractive brochure giving an outline of courses offered, a list of entrance and other scholarships and some notes on careers open to college graduates The faculty of applied science includes departments of civil, mechanical and electrical engineering, mining and fuels, textiles and a school of architecture For some years, every student of engineering who has satisfactorily completed his course at the College has obtained a post, and there are said to be more posts available than students to fill them The Nottingham coalfields provide facilities to students for experience in up to date methods Students of the large and well equipped textiles department also are said to obtain positions readily with very good prospects in hosiery and yarn manufacturing firms, textile testing and research institutions and dyeing and finishing firms

Research Items

Milk and Nutrition

AN interim report to the Milk Nutrition Committee on 'The Effects of Dietary Supplements of Pasteurised and Raw Milk on the Growth and Health of School Children has been published by the National Institute for Research in Dairying The report deals with the data obtained of height and weight at the first and last examinations of a series extending over a year, made on 6 099 school children in Luton Wolverhampton Burton on Trent Renfrewshire and Huddersfield The children were divided into four groups, the first (control) groups received biscuits the second $\frac{1}{3}$ pint of pasteurized milk the third $\frac{2}{3}$ pint of pasteurized milk and the fourth $\frac{2}{3}$ pint of raw milk as daily supplements to their home diets The groups receiving milk showed greater increments in height and weight than those receiving biscuits, and in the case of the children receiving $\frac{2}{3}$ pint of milk increases of 4–6 per cent in height and 9 10 per cent in weight over the control groups were found The response to milk supplements of children initially classed as 'well nourished, appeared to be better than in children of a lower standard of nutrition This may be due to the utilization of the milk in making good structural deficiencies before it begins to affect growth No significant differences could be detected between the effects of raw and of pasteurized milk

Nutrition in an African People

NOTES of observations on the Elmolo of Lake Rudolf, East Africa, made by the late Dr W S Dyson and written up by Dr V E Fuchs his colleague on the Lake Rudolf–Rift Valley Expedition (*J Roy Anthrop Inst*, **67**, 2, 1937), afford material for comparison with the condition of the people when first encountered by Count Teleki and Lieutenant (now Admiral) von Hohnel in 1888 since when nothing has been written about them The contrast suggests that intensive study of the effects of an unsuitable diet on a previously healthy people and of the changed conditions in their mode of life would be of no little interest It was recorded at the time of their discovery that they were approximately five hundred in number In 1934, the number of men, women and children was given as eighty nine only The Elmolo were reputed to be poor members of three surrounding tribes, whose mode of life had been modified by extreme poverty They live principally on fish, varied by occasional flesh of hippopotamus, crocodile and turtle Formerly they were able to obtain a little grain by working, but Abyssinian raids cut them off from their grain supply The only drinking water is from the lake, and as this is deficient in calcium carbonate, there is a calcium deficiency in their diet, which may have some connexion with the universal deformity of the hips from which they suffer This has the appearance of rickets, taking the form of an outward and forward bowing of the tibia It occurs both in adults and in a lesser degree among the children The men suffer more than the women, possibly owing to their more active life The anterior edge of the tibia in many appears to be thickened and rounded, a feature that might be associated with a gradual bending of the bone, causing distortion The pains in the legs from which they suffer they treat with a burning ember placed on a piece of goat skin and held on the limb until it burns through to the flesh

Racial Characters in Jews of Cochin

THERE are in Cochin two groups of Jews White and Black with a third obviously of mixed origin, the Brown all claiming to be descended from Jews who migrated from Palestine on the destruction of the Temple by Hadrian in A D 70 Both groups are in theory endogamous, and the White Jews have evidently maintained their segregation inter marrying closely over a prolonged period while the Black Jews there is evidence to show have introduced low caste Indian women into their community An investigation of the blood groups and the physical characters of the White and Black Jews by Dr Eileen W Macfarlane (*J Roy Asiat Soc Bengal Letters* **3** 1 1937) though dealing with rather limited numbers elucidates several points of historical and sociological interest The distributions of the blood groups in the three Jewish communities are completely dissimilar but the data for the Brown group are disregarded as there are so few The White Jews show a preponderance of Group *A*, due to the very high degree of interbreeding A comparison shows that 1 is high in Jewish communities in the Near East The Black Jews show an even more unusually high percentage of Group *O* Similar high percentages have been recorded only in very ancient races such as the Australians and Amerinds, but there is a similar high percentage among the low castes and outcastes of Ernakulam, among whom the Black Jews have lived for hundreds of years and from whom they have taken wives and concubines Thus evidence from blood groups and physical characters shows that the claims which each Jewish community makes about itself combined with what each says of the other are probably true The White Jews preserve a Near East and European Semitic strain with no Indian admixture while the Black Jews are the descendants of mixed Semitic and native Malayali ancestors

Eelworm Disease of Wheat

EELWORM disease of wheat was first recorded in Egypt in 1919 but considering its distribution at that time it is probable that it had existed in the country some years before In 1926 the areas attacked had increased sufficiently to warrant the need for Government control measures, and although these were successful locally, widespread outbreaks of a severe nature occurred in 1932 A more thorough investigation into the disease, its means of spread and methods for its control were accordingly made, and are now described by G Howard Jones and Abd El Ghani Seif El Nasr Eff (Bull 180, Technical and Scientific Service Ministry of Agriculture, Egypt) From a knowledge of the life history of this eelworm (*Anguillulina tritici*), the almost exclusive means of spread of the disease is from seed containing a mixture of the characteristic hard galls, which form in the ears of attacked plants Under the moist conditions of germination larvæ, which immediately attach the surrounding wheat seedlings, are liberated from these galls. Control measures, therefore, amount to ensuring that seed is free from galls before sowing. Hot water steeping, though successful, is regarded as impracticable on the large scale. The same disadvantage applies to the flotation treatment in which galls can be separated from seed by the difference in their specific gravity in 20 per cent brine. Mechanical cleaning by means of indented cylinders or "trieurs", gave the best results. These machines effect separation by differences in shape, rather than by size or weight, and were found to give an efficiency of more than 97 per cent when used for cleaning eelworm-infected seed.

Angiosperm Embryo Sacs

P. MAHESHWARI (*New Phyt.*, 36, No. 5, 1937) has published a review of the variations occurring in the angiosperm embryo sac. The data recorded represent a considerable search in the literature, and the facts are presented in a more generalized form than in K. Schnarf's "Vergleichende Embryologie der Angiospermen". The method of describing the embryo sacs as monosporic, bisporic or tetrasporic according to the time of origin of the embryo sac relative to the two divisions (reduction division), normally occurring in the megaspore mother cell, is useful for classification purposes. The data contribute little towards the elucidation of the problem of the homologies of the angiosperm embryo sac. Reports from some recent workers that the synergids are derived from one nucleus and the ovum and upper polar nucleus from a second, tend to favour the first part of Porsch's view that the two synergids, ovum and upper polar nucleus, represent one archegonium, but there seems little evidence that the remaining nuclei represent a second archegonium.

Downy Mildew of the Antirrhinum

THE antirrhinum plant, which seems to have largely overcome the menace of attack by its specific rust fungus, has recently been threatened by another fungal parasite, closely allied to *Peronospora antirrhini*. The new attack occurred in Sussex, and Mr. D. E. Green has recently described it (*J. Roy. Hort. Soc.*, 63, Pt. 4, 159–165, April 1938). Symptoms are of the downy-mildew type; infected plants are dwarfed, and the shoots appear somewhat bunched, whilst mealy white patches occur upon the under-sides of the leaves. Conidia and oospores are described; but little more can be said about the disease, for, having regard to the serious nature of attacks in other countries, the Ministry of Agriculture requested, and accomplished, the total destruction of all plants infected in Sussex.

Alaska Earthquake of July 22, 1937

MR. E. H. BRAMHALL has recently given a brief account of this important earthquake in central Alaska (*Bull. Seis. Soc. Amer.*, 28, 71, 1938). Though the country is sparsely inhabited, it was found possible to trace the boundary of the disturbed area, and to show that it contained about 300,000 square miles and that its centre lay near Salcha and probably a few miles to the east of that town. During a flight made over the central region on July 24, what appeared to be a narrow path, about ten miles long and running north and south, was seen a few miles beyond Salcha, but its nature could not be definitely settled. The epicentre of this earthquake thus lay more than 300 miles to the north-west of that of the great earthquake of September 10, 1899, and the shock does not seem to have been felt so far as Yakutat Bay, the central region of the earlier earthquake.

Geology of British Graham Land

SOME indication of the geological results of Mr. J. Rymill's British Graham Land Expedition, 1934–37, are noted by Mr. W. L. S. Fleming in an article in the *Geographical Journal* of June. Geological work was confined mainly to the coast where outcrops could be reached. Only a few specimens were obtained from the interior of Graham Land. With the exception of part of Alexander I Island, the area showed igneous and metamorphic types. Granites and granodorites occupy a large area in West Graham Land, but volcanic rocks are also common. It is clear that the homology with the Andean cordilleras of South America applies to South Graham Land as well as North Graham Land. The eastern coast of Alexander I Island, except perhaps the extreme north, consists of limestones, calcareous grits and shales. Invertebrate and plant fossils were found, but though they were too fragmentary to be identified they seem to resemble, at least as regards the plant remains, specimens obtained many years ago by Dr. O. Nordenskjöld from the Jurassic beds of Hope Bay on the east of Graham Land. This was the only island off the west coast of Graham Land containing unmetamorphosed stratified rocks. All others examined proved to be of the same formation as Graham Land.

Structure of Hailstones

MR. R. P. JOHNSON, of the Research Laboratory, General Electric Co., Schenectady, New York, has sent an account of a fall of broken hailstones in a thunderstorm that visited Washington, D.C., shortly after noon on April 29, 1938. The shapes of these stones and their stratification showed plainly that they were fragments of larger spherical stones about 30 mm in diameter, in which clear and cloudy layers had alternated about every 2 mm. Photographs which appeared in newspapers of the stones that fell elsewhere in this storm showed that these were spherical, and that they damaged greenhouses and the roofs of automobiles. It was concluded that where fracture took place it was at a high level, for the pieces, which ranged up to 15 mm in size, appeared to have terminal velocities suited to their sizes. They did not break on striking the pavement. The absence of layers of clear and cloudy ice built on to each fragment seemed to prove that the stones were fractured below the region where they were formed. The remarkable fact that all the stones were broken at the place of observation, while two miles away only complete stones fell, suggested to Mr. J. Schremp (another of the research engineers of the G.E.C.) that the shattering was caused by a pressure wave that was set up by a bolt of lightning that passed near to them as they fell. These observations are a valuable contribution to the known facts about hailstones that mathematicians who seek to explain their formation must take into account.

New Case of Chemi-luminescence

J. H. HELBERGER reports an interesting new example of chemi-luminescence (*Naturwiss.*, 26, 316, 1938). When the complex magnesium salt of phthalocyanine is added in small quantities at a time to gently boiling tetralin an intense red glow is observed.

The glow remains for a few minutes The process can be repeated until further additions of the compound fail to produce the glow, and the magnesium phthalocyanine dissolves normally with its green colour If now benzoyl peroxide or hydrogen peroxide is added to the liquid in small quantity, or if air is passed through the boiling liquid once more glows It appears, therefore, that peroxides present in commercial tetralin are responsible for the chemiluminescence Other magnesium complexes (for example, the magnesium compound of tetrabenzoporphin) and zinc complexes (for example, those of phthalocyanine tetrabenzoporphin and mesoporphyrin) also give the red glow, but not with such great intensity The copper and iron complexes and the free pigments do not show the effect The phenomenon may prove of interest in connexion with the problem of assimilation

Frosting of Aeroplane Wings

Two dangers of modern air transport are fog and frost deposits on the wings The risk of airport landing in a fog has been practically eliminated by the use of radio beam direction finders and now according to the *Beama Journal* of June two French engineers, MM Rideau and Ducret, have invented a method of de icing the wings by the application of electric currents The main difficulty lay in finding resistances which could be made pliable enough to cover curved surfaces without diminishing the value of the resistance Satisfactory results have been obtained by spraying a colloidal dope composed of a volatile solution, which contains in suspension laminated graphite of low conductivity on the wings The surface was first insulated from the rest of the plane by means of a layer of treated paper Selected portions of the wings were then covered by protecting strips and the remaining surface sprayed with the dope After the wing surface had been covered with the resistant solution the protecting strips were removed and along them by means of a pistol sprayer metallic particles were sprayed to form continuous bands for distributing the electric current As a final protection the whole surface to be treated was painted over with a coating of varnish On the basis of laboratory tests it is claimed that in an aeroplane of 15 metres wing span, normal speed 300 kilometres per hour, the band to which the de icing system should be applied need not be wider than 20 centimetres If the plane were provided with a four kilowatt generator, ice deposit could be prevented up to fog temperatures of 5° C below zero With temperatures 5°, 10° or 15° C below zero it should be possible to detach ice in 50, 90 or 130 seconds respectively

Production of Hydrocarbon Oils from Industrial Gases

DR W W MYDDLETON, in a paper read to the Institute of Fuel on May 12, described the above process developed by Messrs Synthetic Oils, Ltd The chief difference between this and other processes lies in limiting the hydrogenation reaction which leads to conversion of the first product of synthesis (primary' oil) so that motor spirit and Diesel oil are produced without the aid of a cracking plant , at the same time a considerable quantity of material is available for the production of lubricating and transformer oils Also, with this process, it has not been found necessary to adjust the ratio of carbon monoxide to hydrogen in the gas Suitable gas can therefore be obtained from a majority of solid fuels and one plant can handle widely different types The need for coke ovens or supplementary water gas plant is thus entirely eliminated A commercial plant capable of producing 136 180 gallons per day of synthetic oil is in course of erection at Bedlay Colliery near Glasgow, and the results of first trials are awaited with considerable interest

Construction of a Schmidt Camera

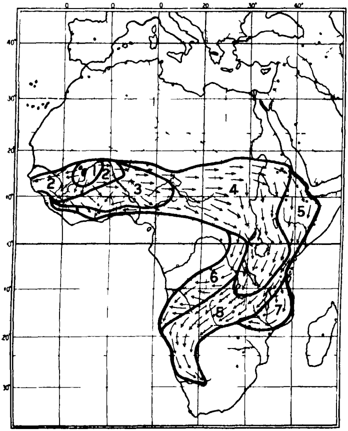
MESSRS H W and L A Cox have recently published a paper with the above title (*J Brit Ast Ass* 48 8 June 1938) which briefly describes the principle of the Schmidt camera and then provides very full details of their own camera constructed on similar lines The grinding of the spherical mirror and also the method for testing the short focus sphere, are described and then follows an account of the making of the correcting lens and the procedure for testing its accuracy Many other details are supplied which will be very useful to those interested in celestial photography and in the construction of a similar instrument and it will repay them to study the paper carefully if they are to avoid numerous pitfalls and difficulties Photographs taken show that the coma is satisfactorily corrected and that the star images over the negative are small Although a slight amount of astigmatism appears at times, as this is probably due to uneven film inferior following, or possibly small distortion in the mountings, it is possible to correct this blemish later

Colour Temperature Variations of Stars

W M H Greaves and E Martin have published a paper entitled Colour Temperature Variations of γ Cassiopeiæ and the Problem of the Yellow B Type Stars in which they give the gradients measured from plates taken in 1926 27 and also the gradients derived from the more recent plates taken in 1936 37, of the above star (*Mon Not Roy Astro Soc* 98 6 , April 1938) The remarkable increase in brightness during 1936 was accompanied by a decrease of colour temperature and a strengthening of the intensities of the emission lines and the same phenomenon took place between the autumns of 1936 and 1937 The change of colour temperature places γ Cassiopeiæ in the category of yellow B type stars to which group Hertzsprung directed attention in 1923 The problem of this type of stars is discussed and the objections to certain theories are briefly stated Previously it was pointed out that the colour temperatures appear to be correlated with the intensities of the interstellar *K* line the low temperature stars having strong interstellar lines, and selective absorption or scattering in interstellar space was suggested as the cause of the reddening effect (*Mon Not Roy Astro Soc* , 89, 125) Gerasimovič criticized this view and showed that some of the stars of the group under discussion were characterized by enhanced emission or diminished absorption on the ultra violet side of the Balmer series limit, and concluded that the low colour temperatures were intrinsically connected with the more luminous stars of B type The subject has been investigated by others, and it is probable that not only is there a reddening due to selective space absorption, but in addition, there is a reddening effect which is intrinsic in the stars and which is associated with the development of line emission Further research on both theoretical and observational lines is desirable

Fourth International Locust Conference

THE International Locust Conferences are held at intervals of two to three years in order to take stock of the progress made in anti-locust research in different countries and to discuss the plans for further concerted action. The Fourth Conference took place at Cairo two years ago, in April 1936, but a full account of its proceedings has appeared only recently*.



SPREAD OF THE AFRICAN MIGRATORY LOCUST

The outbreak originated in 1928 in areas marked by two spots in zone 1, which was invaded during the first year. Zones 2, 3, 4, etc. represent the expansion of the invasion in each of the following years up to 1934. Arrows indicate the main directions of migration.

The Conference proved the world-wide interest in the locust problem, since twenty-three countries were represented (as against thirteen which took part in the Third Conference held in London in 1934), and more than fifty communications were made. The statistical data on the losses caused by locusts in some of the countries were of great interest; the United States reported losses during the ten-year period 1925–34 amounting to about 245 million dollars, and Canada to about 36 millions, while more than 4·5 millions were spent on control in the first named country, and nearly 3·5 millions in the second. Even more staggering figures were presented by the Union of South Africa, where two years of invasion by the red locust cost the country £943,500. Similar statistics collected for all countries suffering from locusts would undoubtedly show that this pest well deserves the attention recently paid to devising better means of controlling it. The Conference entrusted the Imperial Institute of Entomology with the regular collection of such statistical data in future.

The central problem discussed by the Conference was that of the recent progress in the study of the phases in locusts and its practical application. It was agreed that the phenomenon of phase transformation provides a trustworthy basis on which to frame a sound policy for the prevention of outbreaks of locusts and grasshoppers. With regard to the African migratory locust (*Locusta migratoria migratorioides* R. and F.), the data obtained as the result of international investigations centred at the Imperial Institute of Entomology were particularly convincing, since the present invasion has been shown to originate in very restricted areas in the inundation zone of the Middle Niger in the French Sudan. This happened about the year 1928, and in seven years nearly the whole of tropical Africa was overrun by swarms, as is shown in the accompanying map. This evidence induced the Conference to recommend to the Governments of the countries concerned to enter into discussion on the ways and means for the establishment of a permanent organization for the prevention of invasions of this locust in future, by keeping its outbreak areas under expert supervision and by suppressing all incipient swarms. A similar state of affairs was found to exist with regard to the two other African locusts, the red locust (*Nomadacris septemfasciata* Serv.) and the desert locust (*Schistocerca gregaria* Forsk.), although the investigations on those species were at that time not sufficiently advanced for practical steps to be taken.

Another outstanding event of the Cairo Conference was the discussion of the problem as to what extent such activities as agriculture and grazing affect the distribution and mass appearance of locusts and grasshoppers. It was commonly believed, even by some entomologists, that these insects constitute a danger only in the countries with a low level of agriculture, and that their outbreaks become less severe as the country is more highly developed. The evidence presented, particularly by the delegates from North America, led the Conference to the conclusion that, on the contrary, in the case of many species of locusts and grasshoppers, their excessive multiplication and spread have been furthered rather than hindered by man's activities. Therefore, no hope can be entertained for the locust and grasshopper problem becoming less acute merely as a result of a general development of a country. The Conference suggested that particular attention should be paid in all future investigations to the influence on the life and ecology of locusts and grasshoppers of the various forms of human activity such as agriculture, pastoral activity, deforestation, grass fires, etc.

---

* Proceedings of the Fourth International Locust Conference, Cairo, April 22, 1936. Pp. 96+51 appendixes. (Cairo: Government Press, 1937.)

All the aspects of the general theory of locust outbreaks and most of the regional problems were discussed by the Conference, which embodied the results of discussions in twenty-five resolutions and four recommendations based on the facts presented in the papers printed as appendixes to the proceedings forming a large volume of nearly 500 pages.

The next, the Fifth International Locust Conference, will be held at Brussels in August this year.

B. P. U.

Numerical Changes in the German Student Body

By Dr. E. Y. Hartshorne, jun., Tutor in Sociology, Harvard University

OFFICIAL figures for the student body in the German Reich are available up to and including the academic year 1936–37. Frequent alteration in methods of classification and description have obscured the nature of some of the changes and make it difficult and sometimes impossible to interpret them. Only the less equivocal figures are here discussed. For the academic years 1932–33, 1933–34 and 1934–35, these are taken from the official *Deutsche Hochschulstatistik*, vols. 10–14, for 1935–36 from the official *Die Deutschen Hochschulen* vol. 1 (vol. 2 for 1936–37 either has not appeared or is inaccessible in the United States and Great Britain), for 1936–37 from the *Statistisches Jahrbuch für das Deutsche Reich* of 1937. There is reason to believe that the tendencies described below have continued in the academic year 1937–38.

In what follows there are included as students all registered as such, except (*a*) auditors, that is, those not committed to any definite course or examination, and (*b*) foreign students, except where specially indicated.

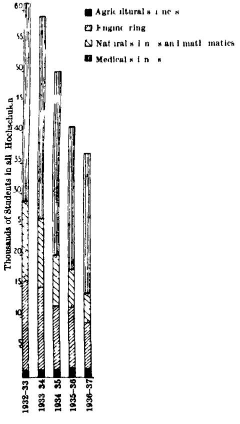
The decrease in the number of students is largely, but not entirely, conditioned by National Socialist policy. There are three obvious factors which have produced a fall in numbers. First, the number of young men in the German population of an age to enter the universities has probably fallen somewhat during these years. Secondly, since 1934 a limit has been set to the numbers admissible to a university education. Thirdly, Jews and so-called 'non-Aryans' have been practically excluded and the proportion of women students has been nominally fixed. The decrease, however, has been much sharper than can be explained by the action of these factors alone.

TABLE 1. NUMBERS OF STUDENTS IN ALL GERMAN *Hochschulen* (UNIVERSITIES, COLLEGES OF ENGINEERING, MINING AND AGRICULTURE, AND SCHOOLS FOR TEACHERS AND FOR CATHOLIC THEOLOGY)

Winter Term	Men	Women	Both
1932–33	97 576	18 578	116 154
1933–34	91 263	15 501	106 764
1934–35	76 961	12 132	89 093
1935–36	70 462	10 976	81 438
1936–37	57 672	9 410	67 082

Thus in the winter term of 1936–37 the total number of students was only 57·8 per cent of the number enrolled before the National Socialist seizure of power in 1933. "Coming events cast their shadows before", since in the academic year 1932–33 this decline had already begun.

In the field of science the accompanying graph shows the development of enrolment for the major groups: (1) agriculture, (2) engineering, (3) natural sciences with mathematics and (4) medical sciences.* The sharp decline of entry in the last three of these practical fields is puzzling. It is easily intelligible that the National Socialist emphasis on increased production from native soil should have raised the number in the agricultural sciences (1,356 in 1932–33 to 1,477 in 1936–37) and also have raised the proportion of students of agriculture to the total entry of students (from 1·2 to 2·2 per cent).



---

* In the category of medical sciences are here included dentistry, veterinary surgery and pharmacy.

The numbers here involved are small But it will surprise most readers that there should be a loss, both absolute and relative, in the number of students in the great departments of engineering and of the natural sciences The number of students in certain science subjects are given in Table 2

TABLE 2 STUDENTS OF SCIENCES OTHER THAN MEDICAL

Winter Term	Engineering	Mathematics with Natural Sciences	Chemistry only
1932-33	14,477	12,951	3 543
1933-34	13,452	10,852	3,504
1934-35	10 310	7,943	3 006
1935-36	9 293	6,493	2,696
1936-37	7,649	4,616	2,058
Percentage change (1932 33 100)	52 9	35 6	58 0

Rearmament has naturally increased opportunities for the employment of highly trained engineers, chemists, etc Nevertheless, the flight from university education in these subjects is unmistakable There are no reliable statistics to show the extent to which the great engineering and chemical concerns are training men on their own account and thus replacing the universities but, for certain departments of science, it is difficult to believe that they can provide courses that are adequate substitutes for those in universities The greater part of the loss in numbers in these subjects, as in the general student body, is probably related to the more numerous and more tempting opportunities and the greater prestige of the expanding fighting services

A peculiar position is occupied by the medical sciences These show a large relative increase, though a considerable absolute fall, in the enrolment While the total number of students in all fields fell in 1936-37 to 57 8 per cent of the number in 1932-33, in the medical field it fell only to 70 2 per cent. In 1932-33, of every hundred students, 27·9 were entered for medical courses By 1936-37 the percentage of medical students had risen to 33·9 of the whole student body, as shown in Table 3 The factors at the back of these changes are complex and would need special discussion

TABLE 3 STUDENTS ON MEDICAL SCIENCES

Winter Term	Total	Percentage of Whole Student Body
1932-33	32,437	27 9
1933-34	33,482	-
1934-35	30,123	—
1935-36	28,383	—
1936 37	22,797	33 9
Percentage change (1932-33 – 100)	70 2	

Unexpected results are yielded by the subjects of 'race science' and pre history, on which very great emphasis is laid in schools and in the general educational system So far as the universities are concerned, these special fields have neither enlisted more than a very small number of native students nor have they attracted any foreign students. For "Vorgeschichte" there were only 59 native and no foreign students, and for "Rassenkunde" there were only 47 natives and one foreign student in 1934-35. After that academic year the numbers of students for these subjects disappear from the available statistics

In fields other than those of the sciences we note the changes shown in Table 4

TABLE 4 STUDENTS IN NON-SCIENTIFIC FIELDS

	1932 33	1936-37.	Percentage of 1932 33 enrolment
Ancient languages	1,225	307	25 1
Modern languages	3,589	842	23 4
Germanistik	3,636	1,540	42 4
Architecture	2,378	1,120	47 1
Journalism	208	353	169 7
Catholic theology	4,208	4,775	113 5
Protestant theology	6 588	2 583	39 2
Education	5 831	8,317	142 5

In 'Education' the number of women is practically stationary The increase in that department has been almost entirely of men It is perhaps explained by the need for 'leaders' in various youth movements

Foreign students are numerically unimportant though they are significant in other ways The numbers of foreign students have been fairly maintained for agriculture (97 5 per cent) and chemistry (94 3 per cent) There have been moderate falls in engineering (to 86 2 per cent) and architecture (to 80·3 per cent) There are much greater falls in law and social sciences (to 65 6 per cent), medicine (to 55 2 per cent), ancient languages (to 42 6 per cent) and 'Education' (to so low as 12 7 per cent) The fall in the total number of foreign students is from 6,693 in 1932-33 to 4,768 in 1936 37. The latter figure is 71 4 per cent of the former which is less change than might perhaps have been anticipated The published figures do not permit us to determine the countries of origin of foreign students We can say, however, that there has been a significant fall in English speaking American students (from 817 to 418, that is, to 51 1 per cent) and a significant rise in Spanish- and Portuguese speaking American students (from 102 to 165, that is, to 161 8 per cent)

Of all the major fields the greatest absolute loss has been in law and the social sciences. Yet despite this loss the Nationalist Socialist interpretation of these subjects is attracting the attention of certain foreign students as the figures in Table 5 show

TABLE 5 STUDENTS OF LAW AND SOCIAL SCIENCES

Winter Term	German Reich Students	Foreign Students
1932-33	24,161	1070
1933-34	20,363	669
1934-35	15,291	621
1935-36	12,617	651
1936-37	9,680	702
Percentage change (1932-33 = 100)	40 1	65 6

On the other hand, for medicine, Germany is ceasing to attract foreign students as is revealed in Table 6

TABLE 6 FOREIGN STUDENTS OF MEDICAL SCIENCES

Winter Term	German Reich Students	Foreign Students
1932-33	32,437	1977
1933-34	33,482	1249
1934-35	30,123	1196
1935-36	28,383	1172
1936-37	22,797	1090
Percentage change (1932-33 = 100)	70 2	55 2

The Constitution of Starch

THE chemical structure of starch has not yet been fully elucidated In recent years evidence as to the size of its molecule has been derived from a study of the products obtained when trimethyl starch is broken down, and it is supposed that like cellulose, starch consists of chains of glucopyranose residues but united by α glucosidic instead of β glucosidic links Haworth has calculated that the molecule of starch consists of not more than 25 30 glucose units and that these units are associated into physical aggregates of much larger dimensions On the other hand, Prof Staudinger has long held the view that the physical properties of starch point to the existence of macro molecules as distinct from molecular aggregates and in the May issue of the *Berichte der deutschen chemischen Gesellschaft* he and Herr Husemann adduce fresh evidence in support of this view from a study of the effect of chemical reactions upon the degree of polymerization of various preparations of starch from wheat

The persistence of a particular degree of polymerization after the starch had been regenerated from an acetylated derivative has been clearly demonstrated and is held to be conclusive proof of the existence of macro molecules The reason why such evidence has not hitherto been available is because these macro molecules are far more sensitive than ordinary molecules to disruptive agencies and it has been shown that even traces of atmospheric oxygen in the solvent exert an enormous effect upon the degree of polymerization

The starch was first freed from phosphoric acid and purified by repeated precipitation by methanol from solution in formamide Osmotic pressure measurements of a solution of this in formamide indicated a molecular weight of 286 000 or a polymerization degree of 1770 Another preparation with a polymerization degree of only 600 was obtained from it by rapid hydrolysis with normal hydrochloric acid The two preparations were then acetylated the former giving an insoluble, the latter a soluble, derivative The acetylated compounds were then hydrolyzed by sodium methylate under very stringent conditions when it was found that the polymerization of the regenerated starches had only been reduced to 1640 and 530 respectively In view of the difficulty of eliminating the last traces of atmospheric oxygen during the alkaline hydrolysis it is claimed that the degree of polymerization of the starch was materially unaltered by the process of acetylation Viscosity measurements led to the same conclusion

Starch appears to be not one compound but a kind of polymeric series From the relation between degree of polymerization and specific viscosity the macro molecules of starch must be quite different in structure from the micelles of cellulose for the viscosity of the latter is 5–10 times as great as that of starch of the same degree of polymerization Since however the viscosity of the solution may be taken as a measure of the length of the dissolved molecules those of starch must be very much shorter and are therefore coiled It is also suggested that the coils are branched and the ends of the short glucose chains are linked in glucosidic fashion with hydroxyl groups of other chains This structure would not only account for a relatively high proportion of tetra methyl glucose among the fission products of tri methyl starch but also for the complete absence of aldehydic properties in starch itself

River Tees Survey

THE beauty and purity of our rivers is a national heritage, and the increasing attention that is being turned towards problems of pollution is therefore welcome But before the causes and effects of pollution can be truly understood it is necessary to have, as a foundation, a knowledge of the natural unpolluted state One of the most important British contributions in this respect is to be found in a recent publication of the Water Pollution Board of the Department of Scientific and Industrial Research* This report is concerned with the non tidal reaches of the River Tees and supplements the work on the tidal region previously published The survey was undertaken by the Ministry of Agriculture and Fisheries, the research staff being under the direction of Dr E S Russell The report is drafted by Dr R W Butcher, Dr J Longwell and Mr F T K Pentelow, who were botanist chemist and zoologist respectively, on the survey

A comprehensive chemical and biological survey was made and many experiments performed in the laboratory on the effects of sewage pollution It was found that the River Tees could conveniently be divided into two regions namely from the source at Cross Fell to the junction with the River Skerne at Croft Bridge a river mileage of 5[illegible] miles and from Croft Bridge to Yarm a distance of 24 miles Above the junction with the Skerne the Tees waters are fairly soft and slightly alkaline, except at periods of heavy flood The flora and fauna in this region are uniform, taking into consideration differences to be expected from type of bottom and rate of flow The only pollution comes from several small sewage works between Middleton in Teesdale and Croft but the dilution by the river is sufficiently great to prevent harmful effects

The River Skerne is however, quite different its water is very hard and it is heavily polluted with sewage effluent from Darlington The Skerne water on entering the River Tees produces a marked change in the chemical and biological characteristics of this lower reach The hardness of the water is increased, as is also the amount of organic matter in solution and in suspension with a resultant lowering of the oxygen content The composition of the flora and fauna is different from that above Croft Bridge, but owing to the presence of nutritive substances from the sewage effluent the numbers of plants and animals are greater By comparing the two regions of the Tees it was possible to discriminate certain organisms as useful indicators of pollution

---

* Department of Scientific and Industrial Research Water Pollution Research Technical Paper No 6 Survey of the River Tees Part 3 The Non Tidal Reaches—Chemical and Biological By R W Butcher J Longwell and F T K Pentelow (London H M Stationery Office, 1937) 12s 6d net

The work opens up a number of questions, not only of economic importance but also of direct scientific interest One of the most noteworthy points disclosed is our complete lack of knowledge concerning the life histories of so many of those insects which form the major constituents in the food of trout and other fish It was found impossible to identify many of the larval stages as these have never been described The necessity for a comprehensive survey of this subject is stressed

The Study of Genetics

ON three occasions recently the Indian journal *Current Science* has appeared as a special issue devoted to a particular topic The third of these, dated March 1938 is devoted to genetics It includes eight short reviews by acknowledged authorities held together by an introduction by Dr Eileen W E Macfarlane

Dr H J Muller writes on The Present Status of the Mutation Theory , discussing the nature and the mode of action of the gene The following section headings indicate the scope of his contribution the gene as the material basis of mutation , the quantitative study of the normal mutation frequency , thermal and chemical influences on the mutation process , the production of mutations by irradiation , effects of mutations on the organism , changes in gene arrangement , and gene mutations as the primary steps of evolution

Prof O Winge gives a very concise and clear review of the facts concerning the cytology of sex He describes his own experiments on *Lebistes* in some detail in order to support his opinion that sex genes are present in all chromosomes and that there is always the possibility that the sex chromosome may become changed into an autosome and *vice versa*

Prof Kihara provides a short article on cytogenetics of species hybrids, whilst Dr H B Frost, in an article on the genetics and cytology of citrus, furnishes a valuable example of the application of these disciplines to the study of a special group of economic value

Special aspects of evolution are dealt with in the contributions by Prof E B Babcock on phylogeny in the light of genetics and cytology and by Prof A F Shull on adaptation in the light of genetics The former stresses the importance of genetics, and particularly of comparative cytology, in discussions concerning phylogenetic relationships between groups of animals and plants, and illustrates his views with references to data from his and his co workers' researches on the genus *Crepis* Prof Shull discusses the possible ways in which adaptation may have arisen through the interplay of mutation and selection, and suggests the lines which future work might profitably take when the problems of selection are being studied genetically

Dr C B Davenport in his Genetics of Human Inter racial Hybrids" stresses the importance of studies of this kind in regions where hybridization is just beginning, so that the first and second hybrid generations may be definitely known He suggests that the regions where such studies might be profitably made are the Amoor River region in Siberia where the Siberians are coming into contact with the Japanese, in certain regions in Africa where the whites are meeting the practically full blooded Negro stock, and in North America where the Eskimo and the white are now newly meeting

The final article is by Dr C B Bridges, who discusses in a most attractive way the future of genetics He is of opinion that the near future will see genetical studies extended to an ever increasing number of animal and plant forms the intensive study of such forms as have so far failed to conform to established genetic principles such studies leading to the consequent extension of those principles and to the invention of new hypotheses and the simplification of the old , the elaboration of new technical methods in genetic experimentation and in cytology the employment of further physical or chemical and environmental agencies in the induction of cytogenetic novelty , the hybridization of genetics and cytology with other sciences such as chemistry embryology, physiology and finally, the progressive clarification of man s philosophical outlook as to his origin, development and activities, with the rescue of still other departments of life from the deistic and vitalistic to the naturalistic and mechanistic realms

Dr Bridges recommends studies of bacteria and viruses and phages for an understanding of gene action and of the nature of sex and points out that the gene now occupies for us the place held by the cell for a previous generation of biologists The gene must be analysed in terms of its physical structure and chemical behaviour For the moment we think of it as a crystalline body, probably of the fibre type, the autocatalytic growth of which is by surface condensation of constituent simpler materials from the surrounding medium, and its reproduction is pictured as a simple split of this fibrous crystal when its growth has exceeded the size limits proper to its internal bonding *versus* the disruption due to temperature and other environmental factors The model of gene structure must allow not only of autocatalytic growth and self reproduction, but also of compositional change and the subsequent perpetuation of that new structure On the hypothesis that the fields of force on the surface of the gene control its crystalline growth, it is conceivable that rare acceptance of a misfit building block would alter the surface material The interpretation of position effects will probably follow the idea that the action of the gene is limited by materials which diffuse into it The induction of changes in the gene and in the chromosome by the use of radiations and of chemical agents is now only just begun By their extended use, problems of the size, number, structure, mutability and action of the gene have become soluble The cytologists may be expected to continue and elaborate their studies of the salivary gland chromosomes, and will proceed intensively to study the phenomena involved in the synapsis, crossing over and distribution of chromosomes to the gametes

Reading these articles, one cannot but be impressed by the extraordinary activity that is everywhere present in the field of genetics, by the luxuriance of its growth, and especially by its promise of great adventure

Science News a Century Ago

Jenner and John Hunter

IN 1838 Dr John Baron (1786 1851), the founder of the Medical Benevolent Society, published his book The Life of Edward Jenner, M D etc Jenner who was born in 1749 and died in 1823 was a pupil of John Hunter, and in the course of a review of Baron s biography of him contained in the *Athenæum* of July 28 1838 the reviewer said Between Hunter and his favourite pupil there was much in common Jenner was a full participator in his master s views and Hunter acknowledged in him a kindred genius Their correspondence in after life was active, and Jenner continued his assistance in the labours of the school by observations experiments and original speculations directed to the development of its favourite objects Trained under such a chief, and possessing an equally ardent love of nature, it is not to be doubted that in whatever circumstances of professional life Jenner had been thrown, he would have made for himself a great name in science, and had he accepted a proposal which was made to him, to join Hunter in the business of lecturing, he could not but have become more favourably known to the medical world than he was as the provincial practitioner and discoverer of vaccination '

Differences between Pears and Apples

'A LONG and interesting memoir has been presented by M Turpin to the French Academy of Sciences , said the *Athenæum* of July 28 1838 on the difference which exists between the cellular tissues of the apple and pear which observations are expected to extend to knots of wood to ligneous kernels, to the calcareous concretions found in the mantle of the Arions, and to the ossification of animals in general Those authors most tenacious concerning the establishment of these two vegetables as different genera have drawn their characters from the adherence of the lower part of the fine styles to their villosity, to the speroid form of the fruit and to the stalk being set in a cavity , characters which are frequently effaced M Turpin founds his on the absence or presence of those stony concretions which are met with in the cellular tissue of the pear

Medicine in Holland

THE issue of the *British and Foreign Medical Review* of July 1838 No 3 contains the following information Holland contains three universities those of Leyden, Utrecht and Groningen Harderwyke and Franecker were formerly the seats of universities but owing to the small number of students at each were disfranchised early in the present century Linnaeus for some time studied and ultimately graduated at Harderwyke , and here were published his *Amoenitates Anatomicae* There are also three subsidised colleges or Athenæums, one at Amsterdam, another at Franecken, and the third at Deventer Each of these has five faculties , and the medical faculties are subject to arrangements in accordance with the general system of instruction established in Holland Owing to its contracted territory and its intimate connexion with other centres, of which the languages are more generally studied and more extensively known, and from which, particularly Germany and France, books are continually imported, the medical literature of Holland is at present rather circumscribed"

University Events

BIRMINGHAM The following candidates have been awarded the degree of D Sc F W Norris for contributions to the *Biochemical Journal* on The Pectic Substances of Plants , Studies on Hemicelluloses Analysis of Carbohydrates of the Cell Wall of Plants , and other papers L I C Northcott for various papers on the structure of metals and alloys in the *Journal of the Institute of Metals Journal of the Iron and Steel Institute* publications of the British Cast Iron Research Association and elsewhere E Preston for papers on Viscosity of the Soda Silicate Glasses at High Temperatures and its Bearing on their Constitution in the *Journal of Glass Technology* Evaporation and Diffusion of Volatile Material into an Inert Gas Stream in the *Transactions of the Faraday Society* and other papers on the technology of glass

EDINBURGH Sir Arthur Olver has been appointed principal of the Royal (Dick) Veterinary College Edinburgh (now affiliated with the University) in succession to the late Principal O Charnock Bradley who died in November 1937 Sir Arthur graduated at the London Veterinary College in 1897 and obtained his fellowship in 1909 He served in the South African War in Egypt and in the Sudan, in 1907 In 1908 he was appointed assistant director general Army Veterinary Services and served throughout the Great War In 1928 30 he was deputy director of veterinary services for India and in 1930 was appointed to the Imperial Council of Agricultural Research of India, from which post he has but recently retired In his last positions he was largely responsible for the reorganization of the veterinary colleges and of veterinary research in India

LONDON University postgraduate travelling studentships of the value of £275 for one year have been awarded to Margaret Elizabeth Broughton (King s College) and Mr Edward Michael Evans (Imperial College—Royal College of Science) Miss Broughton proposes to visit Nigeria and make a study of the land use and native agriculture in the Lower Niger Basin Mr Evans proposes to investigate under Prof Bonhoeffer in the University of Leipzig the synthesis of the sugars under the action of light and in the presence of various catalysts

University postgraduate studentships of the value of £150 for one year have been awarded among others to R J Bray botany (Imperial College), V C E Burnop, chemistry (Imperial College) , M G Church, chemistry (University College) Elizabeth H McPherson, philosophy (University College) , W H Ward engineering (Imperial College—City and Guilds Engineering College)

ST ANDREWS —The Court has agreed to accept the legacy by the late Miss Scott Lang on the conditions attached to that legacy, and has approved a scheme for the erection at the United College of an astronomical observatory and for the appointment of a lecturer in astronomy in fulfilment of these conditions

Dr C A Coulson, fellow of Trinity College, Cambridge, has been appointed lecturer in mathematics in University College, Dundee

Protection of the Fauna and Flora of Africa

If a review is made of the steps which have been taken in the past to safeguard the fauna and flora of any particular country, it will generally be found that whatever has been done, or at any rate originated, in this direction has been almost entirely due to private enterprise or through the efforts of such scientific field societies as happened to be interested in some restricted portion, or individual members, of such faunas and floras. These societies, besides being very numerous, were necessarily of a very heterogeneous character, varying in that respect with the particular field of biological research in which they were more especially interested. They were generally handicapped by lack of funds, lack of public or private interest and consequently lack of means or opportunity for carrying out, *on the necessary scale required*, protective measures adequate for the schemes which they had in view. Each society, moreover, worked in its own limited field, usually without co-operation with other societies.

Thus, although we would not for a moment belittle the pioneering work which has been done in the past, this lack of co-ordination has contributed to a large extent towards rendering that devoted work either ineffective or of far less effect than it might otherwise have been. There has, in a word, been a tremendous output of individual energy, devotion and interest, with an inadequate and often disappointing result.

Fortunately, there has been a tendency in recent years to consider the protection of faunas and floras on a large and comprehensive scale, to realize more and more the essential interdependence of species, and, where protection is needed, to set aside larger and larger areas of country for that purpose. It has been realized, too, that protection on a large and efficient scale connotes international co-operation, that where in the past the efforts of individuals or individual national societies led the way, Governments must now step in and take up the work.

A good example of united action on a large scale has lately been manifest in the International Conference for the Protection of the Fauna and Flora of Africa, held in the House of Lords in May of this year. It was the second conference of its kind to be held, the first having taken place in 1933 in the same building. Both may be regarded as having inaugurated a new policy in dealing with the protection of animal and plant life; for although many international conferences have assembled to consider biological and economic problems relating to the welfare of individual species, none, so far as we are aware, has ever before been set the task of considering from the point of view of its protection the fauna and flora of an entire continent.

The second conference, like the first, was held under the chairmanship of the Earl of Onslow and was opened on behalf of His Majesty's Government by the Marquess of Dufferin and Ava, Parliamentary Under-Secretary of State for the Colonies. It was attended by Government delegates of the Union of South Africa, Belgium, Great Britain and Northern Ireland, Egypt, France, Italy, Portugal and the Netherlands. The interests of the Anglo-Egyptian Sudan were represented by the United Kingdom and Egyptian delegations jointly. A report of the proceedings has already appeared in Nature of June 4. The main object of the second conference was to report progress since the holding of the first conference of 1933; to exchange information, and to engage in exploratory discussion preparatory to a further conference which it is hoped to hold in 1939 An outline of the various delegates' announcements will be found in the report to which reference is made above

In addition to these announcements, however, a report of the Committee of Experts relating to the principal species suitable for inclusion in the Annex to the Convention was handed in, and although for obvious reasons we cannot here consider this report in detail, there are two questions of a general nature to which this Committee has directed special attention, questions which are not easy of solution, and to the discussion of which we propose to devote a good deal of the space available

The first of these questions relates to the method to be adopted to secure protection for species which, owing to their scarcity, require protection over wide areas in Africa, but are so relatively plentiful in certain other areas as not to require protection The second relates to species which in the greater part of Africa do not require special protection, but, owing to special factors, are exceptionally scarce in certain areas, where, therefore, such protection is called for

It was felt by those drawing up the report of the Committee of Experts that species falling into either of these categories could not, and indeed should not, be treated in the same way as species which are extremely rare throughout the whole range of their distribution There will be general agreement among biologists with the Committee's view that some suitable method should be thought out for securing protection on an international plane for species in those parts of Africa where they are extremely scarce although they may be so plentiful elsewhere in Africa as not to call for such protection

It may be added that in this connexion, the Committee of Experts, very properly we think, directed attention to the danger which exists when the population of any given species, or group of species, is reduced to a low ebb ; and that any unnecessary disturbance of the balance of Nature may have far-reaching consequences the ultimate effect of which it is impossible in any given case to foretell

To return, however, to the first question, which concerns species requiring protection over wide areas in Africa but plentiful in certain territories It was brought to the notice of the Committee that there are a number of species found over wide areas in Africa of which all but possibly one or two subspecies are so scarce as to justify being placed in one or other of the categories of the Annex to the Convention This, however, in certain cases has not so far been done, owing to the relative abundance of some subspecies in certain other areas In dealing with this and another very similar type of case, the Committee suggested (1) that there might be included in the Annex itself a direct exception in respect of whatever might be the territory where special protection is not required , and (2) that the Government of the territories in which special protection is not required should follow the precedent set by the Union of South Africa in the case of the aard wolf and the mountain zebra, in respect of which reservations were made by that Government at the time of the ratification of the Convention

Coming to the consideration of species which we may refer to as those of Category 2, namely, those which require protection in certain parts of Africa only, the Committee was struck by the fact that there are a number of species which over the greater part of Africa do not require protection on the international plane, owing to their relative abundance in the majority of the territories concerned On the other hand, in one or more parts of Africa their population is so reduced that vigorous action is necessary Examples are quoted in the Committee's report in respect of the Cape hartebeest, *Bubalis caama*, and the oribi, *Ourebia ourebi*, which, it is understood, the national provincial administration proposes to protect on a scale equivalent to that given to species in Class A of the Annex

It is suggested that these problems, which are mainly concerned with the welfare of mammals, may well be given careful consideration until such time as they may be brought up for final decision at the next conference, which it is proposed to hold in 1939, for they are problems urgently calling for solution

There were other problems of protection, more especially concerned with birds, which the Committee of Experts was called upon to consider One of these was concerned with the recent discovery of species like the African peacock, *Afropavo congensis* Chapin, and the African broadbill, *Pseudocalyptomena graueri* Rothschild Both species are of very great zoological interest , for prior to their discovery the presence of neither peacocks nor broadbills had been suspected in

Africa; both have very restricted distributions indeed, and we may take it for granted that no museum of importance will rest content until it has secured specimens To satisfy such a demand, local 'agencies' will be established, and unless great care is taken there will be over-exploitation with the inevitable and usual result It is to be feared that this commercialization has taken place in the case of the very interesting flightless rail of Inaccessible Island

We are far from advocating any pernickety interference with the privileges of the *bona fide* scientific collector, but we think there should be real and rational control on the part of the Governments concerned in cases of this kind If there were, we should not be faced with the possibility of the extinction of such a biological treasure as the diminutive flightless rail just referred to Until it was discovered by scientific investigators living an almost underground life among the rocks of Inaccessible Island, the inhabitants of Tristan da Cunha had been indifferent to its existence As soon, however, as it was realized that 'there was money in it', its exploitation went on uncontrolled, in a similar way, other relatively rare or unusual animals, such as the African peacock and the broadbill, to mention just two other examples, will quickly be brought to the verge of extinction, unless adequate measures for their preservation are quickly devised

---

Nature and Uses of Rubber Latex

The Chemistry and Technology of Rubber Latex

The Chemistry and Technology of Rubber Latex. By Dr C Falconer Flint Based on Georges Génin's "Chimie et technologie du latex de caoutchouc". Pp xx + 715 + 40 plates (London: Chapman and Hall, Ltd, 1938) 42*s* net

THE fund of information concerning rubber latex has attained its present proportions by contributions from two widely separated sources For many years, excellent work has been in progress in the rubber-producing countries of the East on the physiology and general properties of latex, chiefly with a view to its use as a source of first-grade dry rubber of uniform quality More recently, latex has become available in quantity in the industrial countries of the world, and this has led to intense and detailed study, particularly in Great Britain and the United States, of the problems associated with its use as latex in industrial processes It follows that few men of unquestioned scientific attainments have had working experience in both fields of investigation

Dr Falconer Flint is one of these few After service in the East as a scientific officer on the staff of the Rubber Research Institute of Malaya, he is now working in Great Britain for Imperial Chemical Industries, Ltd, on problems associated with the applications of latex as such It will be with keen anticipation, therefore, that the reader will take up this book He will be hard to please who is disappointed Although the author's original intention was to translate the treatise prepared in 1934 by Georges Génin, he has in reality so amplified and extended it as to constitute the volume under review practically a new work He presents an orderly, thoughtful, and balanced analysis of the literature, including patent specifications.

Proceeding from a historical introduction, the author treats rubber latex first as to its sources, composition, properties, employment as a source of raw rubber (including special varieties such as rubber crumb and powder) preservation, concentration, and transport A later chapter is concerned with the physical testing of latex The large volume of literature to be digested compels a selective treatment in many places, and by the courtesy of the Research Association of British Rubber Manufacturers the reviewer has been able to compare Dr Flint's selected references with those on file in the comprehensive records of the Association's Intelligence Division From this it would appear that the policy adopted has been to quote freely the literature of a subject when that literature is scanty, but to discriminate as the literature accumulates In this way the more familiar tracts of knowledge are adequately treated and space is found fo less familiar matter. For example, attention is directed to the fact that copper is a normal constituent of natural latex as it exists in the tree, moreover, that this copper is associated with the rubber particles rather than with the serum The significance of this as regards the ageing of vulcanized rubber will be appreciated by every rubber technologist, and suggests an investigation into the ageing properties of vulcanized rubber freed from these traces of copper.

Again in the sharply defined subject of surface tension of latex significant in regard to foaming every important reference seems to have been noted When a selection has been imperative what to include and what to omit is a matter of judgment and the selection seems on the whole to have been wisely done In the chapter on the physical testing of rubber latex however in sufficient notice seems to have been taken of recent American research particularly that by Wohler stressing the need for humidity control in tensile testing In this connexion more use might have been made of the opportunity afforded by the chapter bibliographies of including references not discussed in the text as by so doing the work of the reader desirous of following up his study would have been facilitated with no great increase to the cost of production of the book

The latter portion of the book takes up the discussion of the industrial applications of latex—a wide subject indeed with ramifications extending far beyond the confines of the rubber industry This section includes reviews of latex compounding and vulcanization manufacture of dipped goods from latex electro deposition of rubber from latex latex and textiles various other important applications of latex and synthetic latices Here selection has been more severe Thus in the sixteen pages devoted to the vulcanization of latex one is disappointed not to find a mention of the interesting work of Spence and Ferry The insulation of wire and cables by latex processes is dismissed in two and a half pages occupied mainly with a discussion of a single paper The developments introduced by the Simplex Wire and Cable Co (Latox cord) are ignored as are some half dozen general articles and still more patent specifications A book of 88 pages published in the United States last year was devoted entirely to the use of latex in chiropody but this subject is not even mentioned in the volume under review

It is perhaps ungenerous to mention such imperfections since omissions of this kind are almost inevitable in a review of so complex a subject and one in which knowledge is advancing so rapidly We therefore hasten to add that in our opinion it would not be easy within the limits set to improve upon Dr Flint s text Indeed the detail he is able to include is sometimes surprising and indicates first hand familiarity with the subject For example the reviewer was seeking information concerning an obscure detail in the manufacture of latex paper and the desired facts were located immediately on referring to the appropriate section in Flint Moreover he writes concisely clearly accurately and in polished style while his authority is such that his guidance may be followed with confidence

Each chapter concludes with a numbered bibliography There are also author and subject indexes These features will cause irritation to the experienced indexer Strange liberties are taken with proper names both of persons and of companies Small letters and capitals are used with little regard to system Such details though a blemish on the book are not misleading and definite errors are relatively few (the reviewer has noted three) But the author index does mislead It is incomplete in respect of both names occurring in the book and of page references to names entered in the index The subject index is too short to be comprehensive The title of the book also is unfortunate in that it lends itself to confusion with Chemistry and Technology of Rubber recently issued by the publishers of the present work and with the journal *Rubber Chemistry and Technology* Confusion of this kind has already occurred in two cases known to the reviewer

The fact remains that Dr Flint has written the most comprehensive treatise on his subject that has yet appeared and all interested in either the scientific or industrial aspects of latex will be well advised to obtain and use this work Printing and binding are good T H MESSENGER

Patent Medicines in Great Britain

Patent Medicines
By Prof A J Clark (Fact No 14) Pp 98
(London Fact' 1938) 6d

SOME of the facts revealed in this book will come as a surprise to many people Patent medicines is a convenient misnomer for remedies the reputation and sale of which depends more upon advertisement than upon proved efficacy The name of the remedy is protected as a trade mark and vast sums are spent on making the name a household word These advertisements enjoy remarkable legal privileges including specific exemption from the Foods and Drugs Act The publication of fictitious testimonials from bogus physicians is common practice and quite legal The use of fictitious testimonials from real physicians is less common but a physician who sued a firm for this offence lost his case

The proprietors of secret remedies pay a tax and must affix a stamp to each packet This stamp looks like an official guarantee, but since it is only applied to remedies the composition of which is not only secret, but also potentially variable, it cannot possibly be anything of the kind. The tax can be evaded, and secrecy, to some extent, maintained by publishing the composition in a form which the public cannot understand, and considerable ingenuity is shown in the invention of words like 'hydroxyethane' and 'trihydroxypropane' The actual composition is not considered important, and is often decided upon quite casually

Patent medicines do harm by making the nation hypochondriacal, by delaying the rational treatment of cancer and other diseases until it is too late, by wasting the money of poor families when there is incurable disease in the house, and by poisoning Prof Clark omits the tale of the cure for obesity which consisted of living tapeworms, but quotes several authentic cases of widespread poisoning from secret remedies There is no law against the distribution of medicines with unknown properties New synthetic products sometimes have remarkable therapeutic properties, but they should be tested under careful observation before being sold indiscriminately

Various legal reforms were advocated in the strongly worded report of the Select Committee on Patent Medicines which was unfortunately published on August 4, 1914 Prof Clark supports the recommendations of this Committee, and believes that action has been delayed by the fact that the Press derives large revenues from the advertisers of patent medicines and is reluctant to lose this source of income The law is particularly lax in Great Britain

The book is probably an overstatement of the case, and is likely to irritate anyone who actively distrusts the medical profession, but it is much more readable than any dispassionate statement of the facts could have been It is not intended as an attack on all the advertisements of medicines, since the author clearly realizes that important advances in therapeutics have been made in the laboratories of reputable firms, whose incomes depend largely upon advertisement, but whose ethical standard is high. J H G

Trade Cycles

The Mechanics of Prosperity
By Hobart C Dickinson Pp xvi+136 (Baltimore, Md.: Williams and Wilkins Co , London . Baillière, Tindall and Cox, 1937) 9s

WHEN the admitted imperfections of the present monetary system come to be impartially and scientifically investigated, the system advocated by Mr Dickinson in this book will surely deserve consideration The book is directed to American conditions, and does not attempt to give a complete survey , in particular, it scarcely touches at all on the unstabilizing effects of gold—to which Prof Gustav Cassel gave such prominence in his recent book, "The Downfall of the Gold Standard", confirming the views of the late Sir Basil Blackett, in his "Planned Money"

Mr. Dickinson, in contrast to the two authors just mentioned, takes the view that the trade cycle arises primarily from the operation of interest —which in his view is neither completely elastic in rate, and returned to circulation (as assumed in classical economics) nor reinvested and compounded at a fixed rate (as assumed by Marx) It follows that, owing to this 'stickiness' of interest rates, accumulations of unused spending power occur periodically, and cause a temporary inflation which is followed by deflation. During deflation the debts, due to the issue of new money and credits during the inflation period, are wiped out by bankruptcy and defaults, and the cycle begins again

The author's remedy is that the State shall operate as a form of savings bank, accepting money on deposit at an attractive rate of interest when occasion demands, and utilizing the proceeds in the execution of desirable public works by private contract, so that the unused spending power is restored to circulation The State may also 'retire' money In this way the 'work-flow' is kept constant When normal conditions return, the rate of interest on deposits is lowered All deposits may be withdrawn at any time—the Government issuing new money (*not* bonds), without interest, for the purpose , or the Treasury may sell securities

Inflation is prevented by the imposition of taxes on unearned profits (due to rise of price-level) : for example, a national retail sales tax, and a capital gains tax, which are applied automatically, and at appropriate rates, on the rise of price-level of goods or securities, and discontinued when the price-level falls again The author claims that this system of stabilization, which substitutes public works at home for enterprise abroad, avoids the necessity for securing a favourable trade balance, and thus makes for international peace.

The author does not discuss the alternative methods of encouraging spending and preventing the accumulation of unused purchasing power, such as the depreciating money advocated by Silvio Gesel in his book, "The New Economic Order", or the interesting proposals of Dahlberg, in "When Capital goes on Strike"

Some of the present author's conclusions—for example, his objections to taxation for the purpose of providing "social security", such as old age pension, etc —are not in accordance with British experience, and his disregard of the effects of the varying value and supplies of gold (or silver) on price-levels and purchasing power is open to criticism The scheme is clearly described, and constitutes a useful contribution to the growing literature of monetary reform

Elementary Science

(1) Chemistry (with some Geology)
By J. A Lauwerys and J Ellison (New General Science Series) Pp xii + 356 (London University of London Press, Ltd , 1938) 4*s* 6*d*

(2) Introductory General Science
By Dr L M Parsons. Pp viii + 308. (London Macmillan and Co , Ltd , 1938) 3*s* 6*d*.

(3) General Science
By Miss I C. Joslin Pp viii + 360 (London · Macmillan and Co , Ltd , 1937) 4*s* 6*d*.

(4) Elementary General Science
By T. H J Field. Book 1 Pp viii + 200 (London : Edward Arnold and Co , 1937) 2*s* 6*d*.

FOR the past twenty years or so, a movement has been afoot for a more liberal approach to science in the schools, and, although this movement has latterly shown signs of becoming widespread, there are still many masters and mistresses who hesitate to put their belief in it into practice One serious drawback to the wider adoption of courses in general science has been the lack of text-books from which the ordinary work of the laboratory or the classroom might be supplemented or even directed

(1) The chief interest of the first volume named above lies in the insight it affords into the kind of technique which may be employed in the teaching of general science. The title, "Chemistry (with some Geology)", indicates that this is no ordinary book according to standard pattern It is one of a series for which two smaller volumes afford an introduction through the medium of topics The companion volumes in the series proper are concerned with biology and physics. The authors have solved the difficulty of indicating important related matters in the biological and physical fields by a series of cross references, thereby avoiding unnecessary repetition, whilst emphasizing the inter-relationship.

In the selection of subject-matter the book is outstanding, for in this the break with tradition is most marked, and the authors are to be congratulated on a work which must be regarded as a pioneer achievement A consideration of water and solutions introduces ideas of solubility and crystallization, and, following the next chapter on the composition of water, comes a simple treatment of fundamental geology. Here the new emphasis is clearly apparent · chalk, carbon dioxide, carbonates, lime, cement, hardness of water, furring, water softeners, sand, glass, coal, coal gas, coal tar, pass under review, and each arises for discussion perfectly naturally, though in an order which is unorthodox. Then the general process of winning metals from their ores provides a fresh approach to the further resources of the earth Copper, iron and lead are examined with emphasis on their service to man, and a consideration of the protection of metallic surfaces by painting leads to the whole question of the chemical activity of the metals and the subject of equivalence At this juncture, some chemical theory is necessary and the laws of constant composition and multiple proportions, and a simple treatment of atomic weights and valency are introduced

After this pause for consolidation, the sea is considered as a source of raw materials · salt, hydrochloric acid, chlorine, bromine, iodine and fluorine being treated with a refreshing vitality So to the air as a further source of raw materials and to the story of nitrates and ammonia The consideration of sulphur and its uses in industry and a further section of chemical theory mark the end of such chemistry in the book as has normally been regarded as proper in a school certificate course

Much that is found in such courses has been omitted, and the reason is not far to seek the authors have regarded it as of less importance than those matters to which the remaining third of the book is devoted. It is indeed refreshing to find attention being paid here to sugars and starch, cellulose and paper, rayon and celluloid, alcohol and wines, beer and vinegar, esters, fats and oils. Foods, fuels and explosives occupy a further sixty pages before the final chapters on electricity in the service of chemistry, and on light with reference to chemical action. One is left with the impression of a good story well told.

An important question remains to be answered: granting that it is all very interesting, is it not very superficial? Will a pupil be benefited by such a course as it is claimed that he is by one which is narrower but more intensive? A key to the answer to this can perhaps be found in the many questions which follow each chapter. These are a striking feature of a striking book. Those who can answer them will need a sound knowledge of the facts and principles of chemistry and a considerable facility in applying this knowledge to new situations. Stimulating in their originality, these questions represent a noteworthy attempt to produce a conscious transfer of training whereby the pupil will be made to realize that there is chemistry outside the test-tube and outside the laboratory.

While Messrs Lauwerys' and Ellison's book is intended to be used in conjunction with other texts, the remaining three here reviewed cover the whole range of general science. They thus give a clearer indication of the scope which supporters of that subject—if it can be called a 'subject'—consider desirable. Clearly, there is a much wider measure of common agreement than is often supposed. All three books maintain some form of subject division, though sometimes chapters on different subjects follow each other. In all cases, physics, chemistry and biology are the staple ingredients of the diet. In all cases, too, the application of scientific knowledge to everyday activities is made clear and the social importance of science is stressed. Lastly, while generalities are by no means ignored, formal theoretical work plays a much smaller part than has hitherto been thought necessary.

(2) Dr Parsons divides his work into three parts: physics, chemistry and biology. To some extent, his book is an abridged version of his well-known "Everyday Science". The biological sections, however, are almost entirely new and they contain an excellent chapter on the human body in health and disease. The material is up to date, and a great number of applications are described and explained. Some attention is paid to meteorology and to simple mineralogy—these are welcome features. The biological sections, as is now usual, are arranged functionally.

(3) Miss Joslin in her book starts with the earth and the solar system. Though the astronomical section is not extensive, it will be welcomed by children, who almost always find this subject fascinating and exciting. She goes on to consider simple mechanics, physics and chemistry. The last third of her book is devoted to biology, including a chapter on hygiene and the human body. An interesting aspect of Miss Joslin's book is the attention she pays to domestic appliances. Possibly this may prove to be the best avenue through which girls may profitably approach the principles and generalizations of science.

Both of the two foregoing books are attractively written and are obviously the work of experienced teachers. Miss Joslin has included nearly a hundred experiments to be performed by the pupils, and teachers will be helped by the clear directions which she gives. Nevertheless, two important difficulties remain: the material in both books is all of about the same order of difficulty, and the various subjects are rather separated. Teachers will have to use these books rather freely, but this is probably what the authors intended.

(4) Mr Field's book covers the first year only of a general science course, clearly planned on concentric lines. His arrangement is interesting and many of his ideas are novel. He pays much attention to the soil and uses these studies in a very profitable manner. The most interesting part of his book is that in which he deals with biology—the animals of the soil, for example. Here he treats of garden slugs, wireworms, centipedes, tiger-moths, aphis, greenfly, and he adds an excellent chapter on the cultivation of the runner-bean. In fact, most of the biological work he suggests could be done in a suburban back-garden. This is a feature which will be found very useful by many teachers. Furthermore, Mr Field has graded his work well, he gives considerable help to the teacher, and his style is simple and direct.

All these four books illustrate the great advance which has taken place in the production of text-books for schools during the last ten years: they are illustrated by numerous photographs; explanations of simple applications and of familiar things abound; the style of presentation is lively, vigorous and direct. Above all, science is made to appear attractive, and the interests and needs of the pupils receive full consideration. It is clear that teachers of science are beginning to find their inspiration in the everyday world rather than in the somewhat rarefied atmosphere of specialist courses. Further progress, however, is still desirable. Much more, for example, might be done to assist children to transfer scientific modes of thought to ordinary life and to relate the school work more closely to the social background.

The Birds of Kenya Colony and the Uganda Protectorate

By Sir Frederick John Jackson, K C M G, C B Completed and Edited by W L Sclater Vol 1 Struthionidae to Psittacidae Pp. lii+542+10 plates. Vol. 2 Coraciidae to Sylviidae. Pp viii+545–1134 Vol 3 Hirundinidae to Emberizidae Pp viii+1137–1592+6 plates. (London Gurney and Jackson, 1938.) 90*s* net

TO the making of bird books there is no end, and out of the vast bird fauna of Africa there comes continually something new For more than thirty years, Sir Frederick Jackson served his country in East Africa, ending as Governor of Uganda, and all his leisure was spent on safari, mostly in the happy study of the birds He planned a great book, but left it unfinished. It has now been completed with the utmost care and skill by Mr W L Sclater, and, beautifully illustrated by Mr Lodge and Mr. Grunwald, it takes its place beside the works of Reichenow, Shelley, Sclater and Bannerman

In a graceful preface, Lady Jackson tells how her husband on his first arrival in East Africa was cheered by the call of a curlew and gladdened by the familiar sight of sandpipers, oyster-catchers and ringed plovers. It is indeed wonderful to find true swallows, kestrels, nightjars and many another homely bird, not to speak of the all but world-wide osprey and barn owl, all at home in the same land with trogons, barbets, plantain-eaters, guinea-fowl and the endless host of foreign fowl besides. The book is packed full of field notes, straight from the diary of a true field-naturalist. An admirable example is Sir Frederick's account of the great fish eagle (*C. vocifer*), the home of which is on Lake Victoria, and which ranges from the ocean to the Belgian Congo. How its mode of fishing differs from the osprey's is beautifully explained; and the zoologist will be interested to know how it catches perch, catfish and an occasional lungfish (or *Protopterus*), but leaves the last uneaten ! The hammerhead (*Scopus*), the ground hornbill and several of the sunbirds are a few more among the countless examples of Sir Frederick's powers of observation and description The book is a fine memorial to a modest and a useful life.

Outline of Historical Geology

By Dr. A K Wells. Pp. xiv+266 (London George Allen and Unwin, Ltd, 1938.) 12*s* 6*d* net

DR. WELLS'S new book, although essentially a text-book of stratigraphy, is something more than a formal descriptive catalogue of the various divisions and subdivisions of the geological column. It is an excellent general account of British stratigraphy, pleasantly written in the form of a continuous narrative, and very fully illustrated by line drawings, many of which have been specially prepared.

The book is expressly intended for beginners in geology, either undergraduates about to commence a course in this subject, or general readers who wish to acquire a knowledge of geology for cultural reasons. The author's experience as a lecturer is sufficient guarantee that the text is suitable for the first class of reader, but it is rather doubtful whether the needs of general readers with absolutely no previous knowledge of the subject are adequately met

Such readers would surely be curious about the various geological processes that have operated in past ages to produce the rocks that now form the earth's crust This branch of historical geology is, however, rather summarily dismissed in the short introductory chapter (further references to geological processes are, it is true, made in the text, *en passant*) A more complete account of these processes seems desirable in order that uninformed readers may fully appreciate the details of stratigraphy, with which 'historical geology' is largely concerned Again, although technical terms have been avoided wherever possible, a general reader would probably appreciate a glossary in explanation of some that are used

Apart from beginners, specialists in other branches of geology will find this work provides an excellent refresher course in stratigraphy, and it should be appreciated by a wide circle of readers.

Comprehensive Index of the Publications of the American Association of Petroleum Geologists, 1917–1936

By Daisy Winifred Heath Pp vi+382 (Tulsa, Okla American Association of Petroleum Geologists, London Thomas Murby and Co, 1937) 13*s* 6*d* net

THE comprehensive index to the first twenty volumes of the *Bulletin of the American Association of Petroleum Geologists* is a fitting tribute to the work achieved by the Association during the first two decades of its existence In 1917, the production of petroleum in the United States amounted to approximately 355 million barrels, whereas in 1936 it exceeded one billion barrels The first volume of the *Bulletin*, issued in 1917, contained 176 pages, whereas the twentieth volume contains 1868 pages This in itself is proof of the efforts made by the Association to further the search for oil and aid its scientific development during these years. The value of the work has been immeasurably enhanced by the compilation of an index, which facilitates reference to all publications of the Association during the period 1917–36

Numerical Problems in Advanced Physical Chemistry

By J. H. Wolfenden Pp. xx+227. (Oxford: Clarendon Press, 1938) 7*s*. 6*d* net.

MOST teachers of advanced physical chemistry will have felt a need of a collection of examples taken from modern publications on such subjects as photochemistry, dipole moments, activity coefficients, kinetics and molecular spectra. Mr. Wolfenden's book contains an adequate number of such exercises with answers and explanatory notes, although for the theory the reader is referred to textbooks. The book is attractively produced and its price is very moderate. It may be recommended as likely to prove very helpful both to teachers and to students.

Les Instruments de Musique de Madagascar

Par Prof Curt Sachs (Université de Paris Travaux et Mémoires de l Institut d Ethnologie, 28) Pp ix + 96 + 15 plates (Paris Institut d Ethnologie 1938) 37 50 francs

THIS study of the musical instruments of Madagascar by Prof Sachs, the well known authority, fills a gap in the study of primitive music, which in itself is not a little remarkable As the author points out, ethnographical museums and collections of musical instruments are singularly ill supplied with specimens from this source The Musée du Trocadero, however, or the Musée de l Homme as it is now called, possesses a collection of nearly two hundred examples Prof Sachs, accordingly has prepared a *catalogue raisonné* of the collection and in order to make his study as complete as possible, has supplemented it with a description of types to be found in other collections, or if not otherwise available, recorded in the literature

In view of the ethnic composition of the people of Madagascar in part African, in part of Malayan origin, and keeping in mind its geographical position which has made it from early times accessible to all the seafaring peoples who traversed the Indian Ocean, it is not surprising to find that the musical instruments are of a varied character and mixed origin African, Malayan, Indonesian, Arab and European Nor is it safe to infer that when an instrument has been traced to its place of origin, it has reached Madagascar direct It may have come for example by way of India Hence it will be seen that the task which Prof Sachs has set himself of constructing a chronology is by no means simple One very interesting point which emerges in connexion with the instruments from Malaya The absence of the Javanese gong and other bell like Indonesian types leads to the conclusion that the Malayan instruments cannot have been introduced in the island later than the beginning of the Christian era

Elementary Mathematics for Electrical Engineers

By Sir Ambrose Fleming Pp 110 (London George Newnes, Ltd , 1938) 5*s* net

THIS handbook of mathematics is designed to provide the engineering student with just those practical parts of the subject which are of the greatest importance to him The subject matter, arranged in ten sections, ranges from simple to differential equations , from the elements of trigonometry to hyperbolic functions and from plane co ordinate geometry to vector algebra and harmonic analysis There is a commendable continuity in the treatment of such a variety of topics, the connecting link being naturally the calculus, which is the foundation of engineering calculations

The section on quadratic equations may prove somewhat confusing as an x is missing in several places on p 16, and in the following paragraph, the condition for *one* real root is explained after the existence of *two* roots has been well illustrated

There are few exercises for the student, but many of the basic principles are well applied to some interesting and really practical problems Some useful tables are given at the end by the use of which numerical calculations may be facilitated The engineering student should find this a very useful book, in spite of its brevity, and if he makes himself thoroughly acquainted with its contents, he will be able as the author hopes, to continue his mathematical studies from more advanced works on mathematics

The League from Year to Year (1937)

Pp 246 (Geneva Information Section, League of Nations , London George Allen and Unwin, Ltd , 1938) 1*s*

UNDER the title The League from Year to Year (1937) the Information Section of the League of Nations Secretariat has issued its annual survey of the League s activities in 1937 This volume of 246 pages gives a clear and concise review of all the main activities of the year in sufficient detail to emphasize the value and significance of the technical co operation which is being maintained in spite of the deterioration in the international political situation

Scientific workers should find in the volume much material to facilitate the study of technical questions in which they are specially interested The chapter on communications and transit, for example, refers to action taken in relation to oil pollution at sea and in regard to road transport A separate chapter is devoted to nutrition, while the chapters on the Health Organization and on intellectual co operation indicate very clearly the significant contribution to human welfare that is being made in those fields

Other chapters deal with mandates, the Permanent Court of International Justice economic and financial work, the protection of minorities, opium, social questions etc a detailed chronological table of the chief events of the year so far as the League is concerned is also included

Commonwealth Bureau of Census and Statistics, Canberra

Official Year Book of the Commonwealth of Australia No 30, 1937 Prepared by Dr Roland Wilson Pp xxvii + 1021 (Canberra Government Printer, 1938) 5*s*

THE Commonwealth Year Book is always most informative It contrives, mainly through the medium of statistics, to give a view of Australian life as a whole It would be difficult to find any important aspect of Australian activity that is omitted from its pages, and where considerations of space demand curtailment of treatment, full reference is given to relevant publications In many aspects also the statistics are all the more useful since comparable statistics are given for other States

The book contains a number of maps, including an average annual rainfall map, an air route map, a railway map and a map of artesian basins The number of artesian and subartesian bores increases only slowly, but on the other hand the area irrigated by surface water has grown in several States As usual, a long list of books on Australia appears

Ice

By the late Dr A E H Tutton, FRS

THE subject of Sir William Bragg's Friday evening discourse at the Royal Institution on March 18 last is one which is of deep interest from a remarkable variety of points of view among them that of the crystallographer the physicist the geologist the climber the ski runner the plumber the food purveyor and distributor and even the very housewife herself Moreover it is one which has proved of unusual difficulty although it concerns natural phenomena of the most familiar kind and one of the most abundant substances in Nature Indeed we never seem to get a thorough and complete understanding concerning the extraordinary nature and unusual properties of ice although they have been investigated and discussed for ages Only quite recently an Association for the Study of Snow and Ice has been formed in Great Britain now numbering about eighty members the nucleus being the British members of the International Commission of Ice and Snow which deals with the survey of glaciers and the prevention of catastrophes due to them One of the latest discussions at the London meeting of the Association concerned The Structure of Flow of Glacier Ice

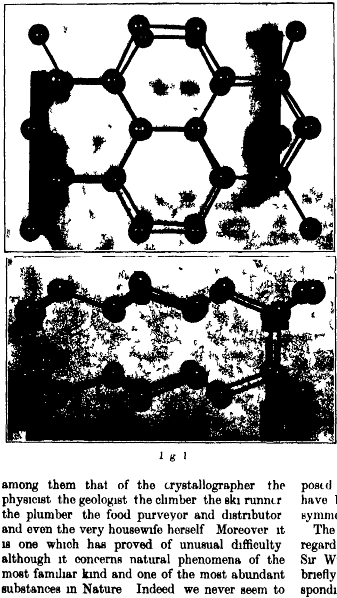

Fig 1

One property of ice its crystal form and structure and especially the system of symmetry to which it belongs has however now after long discussion been settled a satisfactory conclusion mainly derived from the X ray analysis of ice crystals which we owe largely to Sir William Bragg himself For ice is now definitely known to crystallize in the hexagonal system and in the holohedral class exhibiting the full symmetry of that system the dihexagonal bipyramidal A whimsical yet very beautiful illustration of this fact is afforded by one of the exquisite photographs of snow flakes taken in a severe winter on the other side of the Atlantic by Mr Wilson Bentley one of the four thousand which we owe to his genius no two of which are alike while all exhibit the same symmetry For this particular snow flake of the plate like rather than the feathery star like kind resembles almost ridiculously closely a grandfather clock face in its case with twelve markings very like Roman numerals in exactly the positions of the twelve hours These twelve markings correspond to the dihexagonal character of the crystal for if the symmetry had been merely trigonal as so long supposed one would have expected the markings to have been only six corresponding to ditrigonal symmetry

The crystallographic facts now definitely known regarding ice crystals due to the work of Dennison Sir William Bragg and Prof Barnes may very briefly be stated The space group is D_6^4 corresponding to the class already mentioned There are four molecules of water in the unit cell of the structure the dimensions of which are $a = 4\ 53$ A $c = 7\ 41$ A The ratio of the axes is $c\ \ a = 1\ 634$ This structure remains unchanged for all temperatures between 0° C and − 183° C The density of the crystals is 0 9168 and their cubical expansion coefficient is 0 00016

Sir William now regards the ice crystal as a set of parallel sheets of puckered hexagons as shown in the photograph of a model reproduced in the upper part of Fig 1 the observer being supposed to be looking along the optic (hexagonal) axis perpendicularly to the basal plane The sheets are connected by links perpendicular to them The balls in the photograph (and model) are supposed to be oxygen atoms for as hydrogen has so little effect on X rays owing to its extreme lightness the position of the hydrogen atoms is even yet not quite certain although there is great probability that they lie between the oxygen atoms alternately with them in such a manner as causes the hydrogen atoms to be double in number to the oxygens The second photograph in the lower half of Fig 1 was taken at right angles to the upper one showing two sheets the observer looking along the basal plane Each oxygen atom lies at the centre of a tetrahedron of which the four corners are occupied by other oxygen atoms The distance between adjacent oxygen atoms is 2 74 angstrom units whether in the same sheet or two neighbouring sheets

Sir William directs attention to some singular experiments in 1936 by McFarlan as to the effect of pressure on the structure from which it would appear that under high pressures ice changes its structure somewhat forming in succession two different forms II and III and two other photographs were shown in the lecture reproduced in Fig 2 of form II While the sheets remain much the same they are brought nearer together by the pressure as shown in the lower half of Fig 2 In form III the sheets also give way

Tamman in 1910 first observed this remarkable fact and showed that the forms II and III are solids at the low temperature of liquid air by actually removing them from the steel high pressure cylinder after releasing the pressure The new solids rapidly changed into ice with a large increase of volume at the ordinary atmospheric pressure Bridgman in 1912 confirmed Tamman s facts using pressures up to ten thousand kilograms per square centimetre McFarlan has taken the matter further by obtaining X ray analyses of these two forms II and III at the low temperature of – 155° C and concludes that they are polymers of ice, having eight molecules of water to a side centred orthorhombic cell in the case of II and sixteen molecules to a body centred orthorhombic cell in the case of III McFarlan appears to have found pressures up to 2100 atmospheres adequate for the production of these two new forms of solid water He gives the space group of II as $V^5-C\,222$ and the cell dimensions a 7 80 A b – 4 50 A and c 5 56 A and for III the space group V_h Ibmm and the dimensions a 10 20 A b 87 A and c 7 17 A

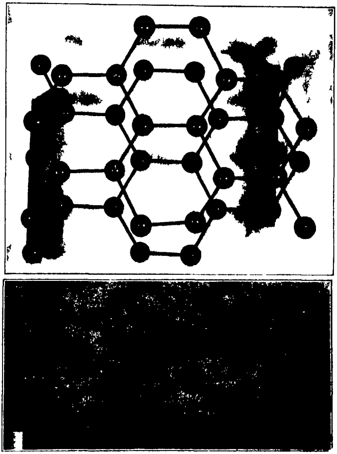

Fig 1

The slip or glide plane of ice made known in 1891 by the work of McConnell of Cambridge a frequent visitor to Davos for health reasons and fully confirmed by all recent work to be parallel to the basal plane is due to the readiness with which the sheets of hexagons although puckered can glide over one another Moreover water freezing in an open pond or vessel crystallizes as a plate parallel to the basal plane Hence McConnell in order to test the plasticity of single ice crystals cut some bars of ice from single crystals from a frozen lake surface the bars being several inches long and an inch or so wide and deep Each was supported in turn near its two ends and a weight was suspended by a loop from its middle When the bar had been cut with its length parallel to the basal plane and the water surface, and was arranged on the supports with its upper surface also horizontal, parallel to that same plane, a little bending occurred when the weight was placed in position, but it was only elastic bending, and the original position was restored on removal of the weight. If the bar were turned over on its other side, with the basal plane now vertical, practically no bending at all occurred on adding the weight. But if the bar had been cut from a very thick plate of pond ice, so that its length could be made to be perpendicular to the basal plane, then on adding the weight the bar sagged continuously in the middle, taking a V-shape with a more and more acute angle, owing to the glide plane having full freedom of action, the sheets of hexagons readily gliding past each other. The deformation was, moreover, permanent to almost the complete extent. Indeed it seemed at first as if this newly discovered property of the glide plane might afford a better explanation of the movement of glaciers than regelation. For a glacier is a conglomerate of single crystal grains, closely fitting together, with irregular bounding surfaces instead of crystal facets.

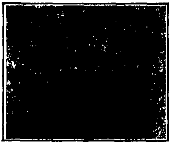

Fig. 3

Even this was not the only additional factor required to supplement the inadequate regelation principle of Faraday (the freezing together of freely floating pieces of ice on contact) and Thomson and Tyndall (the liquefaction under pressure and re-freezing on removal of the pressure). For the crystal grains are usually promiscuously orientated, neutralizing each other's glide-plane movements. But subsequent researches showed that the irregular bounding surfaces are in reality liquid films, the pressure occurring from time to time during the glacier's movement down its unevenly inclined bed being most effective at these boundaries. Hence, molecular transpiration across them occurs, the crystal grains growing in size as the glacier descends, so materially indeed that while it is microscopic in the upper reaches, the 'firn', it may be as great as a yard or more at the snout of the glacier.

Of course Sir William emphasized the fact that the liquefaction of ice by pressure is rendered possible by the very open structure of ice, as revealed by X-rays, which also accounts for the abnormal expansion (instead of contraction) of water on freezing. I would like to add that it is even yet rarely appreciated how immense is this volume change which occurs on the freezing of water, compared with the thermal expansion of either ice or water. That of ice has already been mentioned (0·00016), and that of water is not far different; between 7° and 8° C. it is 0·000053, between 10° and 11° it is 0·000091, and between 19° and 20° it is 0·00021, the average coefficient between 10° and 20° and also the actual coefficient at 15° being exactly 0·00016. For the interesting interval between the maximum density at 4° (or more accurately 3·945° C.) and 0° (without freezing) the total expansion of the water is only one ten-thousandth of its bulk. But when freezing occurs there is a sudden expansive leap of nearly one-tenth of the whole volume of water frozen. The 'water-flowers' (Tyndall's 'ice flowers') or negative ice-crystals, produced in a slab of lake-ice by passing through it the hot rays from an electric lantern, are particularly interesting as illustrating the foregoing fact most elegantly, for they always exhibit a vacuole about their centre, of about one-ninth of the water content in the whole star-like cavity. Sir William exhibited a film which had been taken at the Royal Institution of this phenomenon, and Fig. 3 reproduces one of the best of these six-rayed 'flowers' shown by the film.

At the recent meeting of the Snow and Ice Association already mentioned, Dr. C. H. Desch emphasized the necessity of distinguishing between plastic and viscous flow. He pointed out that the former means an immediate yield under constant stress, and quoted Ruskin's example of butter (plastic) and honey (viscous), as an excellent illustration of the difference. He also showed that no formula can be found for the flow of glacier ice because flow is here complicated by recrystallization. He also propounded the question as to whether, in the production of a crack in ice leading to the formation of a crevasse, the fracture occurred between the crystals or along the basal planes (glide planes) within the crystals. In this connexion, I well remember being present at the startling event of the birth of a crevasse. It occurred during a crossing of the Alphubeljoch from Saas-Fee to Zermatt, in company with Alessandro Corsi of Macugnaga. Suddenly there was an explosion like a rifle shot fired at one's feet, at which both of us leapt forwards (the rope being taut between us). On recovering our equanimity and looking down at the glacier surface, which at that spot had been unusually free from crevasses, we perceived a thin sinuous line of crack extending as far as we could see on each side of us, which obviously, before our eyes, opened more and more, until as we left to resume our climb this new crevasse had widened to more than a couple of inches

The chairman of the Association, Mr Gerald Seligman, quoted recent work indicating that the individual crystal was the unit of glacier movement, and that the slightest differential movement of the crystal grains might well be one of the principal causes of glacier movement It is to be hoped, and indeed expected, that confirmation or otherwise of this view, and the answer to Dr Desch's question, may be forthcoming from the investigations now proceeding at the Jungfraujoch by Mr Seligman and his collaborators

In conclusion, it appears to me that practically every seriously suggested cause for the movement of glaciers that has ever been put forward does operate, each playing its part when the conditions are favourable to its operation, and several of them usually acting simultaneously This opinion is not merely the result of an attempt to digest all the voluminous records of practical scientific work on glaciers, but of personal study commenced so long ago as the year 1891, materially assisted by careful examination of nearly two thousand photographs of ice and snow formations on glaciers and mountains, taken by me personally during more than thirty seasons spent in the Alps, besides visits to the Rocky Mountains and the Himalayas

Cambridge Meeting of the British Association

General Arrangements

THE Sectional programmes for the Cambridge meeting of the British Association were outlined in NATURE of July 16, it remains to add some general remarks to the notice which appeared in these columns when the preliminary programme was issued last April

The attendance promises to be large it should well exceed the average figure (which, since, but excluding, the centenary meeting in 1931, is 2,274), and this despite the unusually early, and to some members rather disconcerting, date of the meeting, August 17–24 This was inevitable, in order to meet the convenience of the colleges which are so generously offering their accommodation to visitors Those who remember the last Cambridge meeting, in 1904, may recall that it fell on exactly the same dates, for the same reason Nevertheless, the attendance then was 2,789, a very high figure for those days, but one which the present officers (and especially the General Treasurer) would very gladly see surpassed this year It may well be, however, that the indulgence of late-comers will have to be sought if there be not room for them all to hear Lord Rayleigh's presidential address on August 17 The same drawback supervened in 1904, when many were unavoidably excluded from the Corn Exchange in which Mr Arthur (afterwards Lord) Balfour as president inaugurated the meeting. On the present occasion the address will be given in the Regal Cinema There is more room there than in the Corn Exchange (and certainly those present will listen in conditions of greater comfort); but there may not be enough for all members. It has therefore been decided to number and reserve all seats and to issue tickets early next month to members according to priority of their intimation to be present, any who receive tickets but who do not intend to use them will be besought to return them at once in order that they may be made available for other members Consideration is being given to the desirability of relaying the address to another hall, a facility not available to the harassed officers in 1904

The general arrangements are nearing completion, and an ample list of excursions and visits has already been issued to those who have intimated intention to attend The full programme and timetable, together with the specially compiled scientific survey of the Cambridge district, will be sent out as usual some ten days in advance of the meeting

In recent years, the Association has attempted to meet a widespread demand for more specific attention to the direct relations between science and its bearing upon the life of the community, by the simple method of indicating in the programme all communications which bear specifically on this question There will, however, be presented to the Council and the General Committee important proposals to place the study and presentation of this aspect of the advancement of science in a more clearly defined position within the Association It will be recommended that a Division for the social and international relations of science be established—the Council having already approved this step in principle, and has appointed a committee to consider and report upon the method of working the new Division The inclusion of international relations is made with the more confidence because the interest of the American

Association for the Advancement of Science in these questions is well known and a representative delegation from that body is expected at Cambridge to confer with the officers of the British Association upon the ways and means of closer co operation The report of the committee will be circulated early in August to all members of the General Committee known to intend to be present at the meeting The same committee of the Council was charged with a review of the methods of publication at present practised by the Association the principal medium being the annual report which many people have long regarded as a graveyard of scientific communications the relegation of which thereto not infrequently appears to be something less than they deserve A far reaching proposal will be put forward in this connexion

It will be apparent from previous announcements that the scientific programme will be full of worthy subjects and one not previously mentioned calls for notice here The visit of the scientific delegation to India last winter was so notable an episode that it has been felt to call for due recognition at Cambridge and it is hoped to hold a special meeting with Sir James Jeans the jubilee president of the Indian Science Congress Association in the chair at which some of the delegates will give their impressions of the tour Also an exhibition of photographs taken by delegates will be displayed in the reception room the party was fortunate in including a number of very skilful amateur photographers Another unaccustomed exhibition will be that of paintings and drawings by members of the Association some of whom are already well known as artists in their hours of relaxation though hitherto there has been too little opportunity to appreciate their work

In certain directions therefore the Cambridge meeting may be expected to add materially to the history of the Association In one other it will assuredly do so For the first time a sherry party finds place in the official programme It will be given in Emmanuel College by the Mayor and Mayoress of Cambridge a very welcome innovation

Among other social functions will be a reception by the University in the Senate House and Old Schools on Thursday evening August 18 There will be informal conversaziones in Trinity College on Friday evening August 19 and in St John s College on Monday evening August 22 Garden parties will be held in Downing College and Sidney Sussex College on Friday afternoon August 19 and in Christ s College and Queens College on Monday afternoon August 22

Full details of the social functions will be published in the programme and time table

---

The Piltdown Man Discovery

Unveiling of a Monolith Memorial

ON July 23 Sir Arthur Keith unveiled a monolith memorial which has been placed in the grounds of Barkham Manor Piltdown Sussex to mark the spot where the late Mr Charles Dawson found the fossil skull of Piltdown Man (*Eoanthropus dawsoni*) He paid a tribute to Mr Dawson whose important work as an amateur deserved our gratitude and remembrance He remarked that the Piltdown skull is so different from any other human skull previously discovered that the divergent opinions expressed by those who have attempted to interpret it are not surprising In 1912 1913 when the fossil was found much less was known of early man than is known at present If a similarly novel discovery were made now there would be closer agreement among those who studied it Sir Arthur is more impressed at present with the simian characters of the skull and brain cast as well as those of the lower jaw than he was when he originally examined the fossil

After the unveiling Sir Arthur Smith Woodward gave some reminiscences of his collaboration with Mr Dawson at Piltdown and he added that the first subscription towards the memorial was received from the late Prof Henry Fairfield Osborn of New York Brigadier General E G Godfrey Faussett chairman of Council of the Sussex Archæological Society spoke of the generosity of landowners to archæologists and expressed thanks to Mr D Kerr of Barkham Manor The memorial was designed by Mr Percival Bridgman of Lewes and is made of durable Carboniferous sandstone from Yorkshire

The following is the substance of Sir Arthur Keith s speech

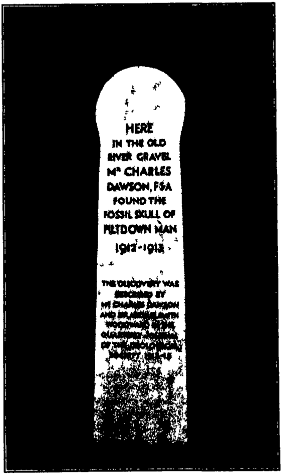
Mr Charles Dawson—solicitor and antiquarian—has been in his grave these twenty two years , he died in 1916 at the age of fifty-two but the discovery he made on the spot where we are now assembled, the fossil remains of the earliest Englishman known to us, goes on growing in magnitude and in importance. The fossil bones he gathered here from a heap of road metal by the wayside the private way leading to Barkham Manor—gave us the entrance to a long past world of humanity such a world as had never been dreamt of by anyone in England or in any other land.

I have in my hand a guide book to Sussex published in 1911. It was written by my learned friend the late Mr. A. R. Hope Moncrieff. He assured his readers that the earliest inhabitants of Sussex were the celtic tribes whose camps can still be traced on the Downs. When these words were being written by Mr. Moncrieff, Mr. Dawson was assembling evidence that carried the history of man in Sussex back to a remote period—one to which geologists assign a duration of half a million years—or perhaps twice that amount. This discovery was not sent to Mr. Dawson by the fickle goddess chance; it came to him because knowledge knew how to use its opportunities. The Weald was then alive with antiquaries searching for the handiwork of ancient man. Mr. Dawson had his own beat, and searching for implements in that beat he met with the fossil remains of a maker of the older stone implements.

The greater the novelty of a discovery the more it departs from ascertained knowledge the greater is the difficulty of getting it into its right perspective and the longer is the time needed to reach that end. More than ninety years ago an exciseman named Boucher de Perthes found worked stone implements in ancient deposits in the Somme Valley; it took seventy years to prove that what was true of the ancient deposits of the Somme Valley is repeated in every great river valley of the Old World. In 1857 when Neanderthal man was discovered, diverse explanations were given to account for the brutality of his structure; it took half a century of exploration to place him in his proper place in history. He proved to be a representative of the Europeans of a remote period the period which saw the onset of the last glaciation of Europe.

The fossil remains found at Piltdown by Mr. Dawson set students of man's evolution the most difficult task that has confronted them hitherto. In his characterization, Piltdown man was quite unlike any fossil type known to us. Sir Arthur Smith Woodward was impressed by his simian similarities; I, on the other hand, was impressed by those features which, as I thought then, were eminently human and modern. Hence arose those discrepancies between us—discrepancies of a quarter of a century ago.

Since then, much has happened. Discoveries are being made which help to throw Piltdown man into his proper place in the crowded throng of evolving human forms. We now know that when the Piltdown type was being evolved in England—or at the western end of the Old World—a totally different type had come into being in the Eastern lands of the Old World. The Eastern types had low receding foreheads, modelled as in the gorilla and chimpanzee. The Western or Piltdown type differed; it had a relatively upright and high forehead, modelled not on gorilla lines but rather on those of the orang. While the Eastern forms retained in their shape of head the low squat type of the chimpanzee and gorilla, the Western or Piltdown type tended to assume the higher vaulted skull seen in modern races. There is no denying that in many of his features Piltdown man foreshadowed some of the structural modifications we find in modern races of mankind. Sir Arthur Smith Woodward, I know, will agree with me as to how Piltdown man came by such features: he came by them independently, for discoveries of recent years have proved that diverse races of mankind have undergone the same structural change quite independently of each other. And there is also no denying that through all his known parts there runs a simian vein in Piltdown man, in his skull and brain as well as in his mandible.



Reeves photo Lewes

So long as man is interested in his long past history, in the vicissitudes which our early forerunners passed through, and the varying fate which overtook them, the name of Charles Dawson is certain of remembrance. We do well to link his name to this picturesque corner of Sussex—the scene of his discovery. I have now the honour of unveiling this monolith dedicated to his memory.

Obituary Notices

Mr C F M Swynnerton, C M G

THE recent death of Charles Francis Massy Swynnerton, as a result of an aeroplane accident in Tanganyika Territory on June 8, has been a heavy loss to science and especially to all who are interested in the development of tropical Africa, and it is particularly deplorable in that it occurred at a time when he had just been placed in a position to apply on a much larger scale the scientific ecological methods that he had devised for the control of tsetse flies

Swynnerton was born on December 3, 1877, in Lowestoft going to India later where his father was senior chaplin to the Indian Army, his mother being the daughter of Major W H Massy, of Grantstown Hall, Tipperary He was educated at Lancing College and went out from there to Southern Rhodesia at the age of nineteen years, where for many years he was engaged in farming in the Melsetter District, then generally known as Gazaland

Being a very keen all round naturalist, Swynnerton soon turned his attention to the birds of that area, and during 1907 and 1908 he published a series of papers (250 pp) in the *Ibis* recording his observations Owing largely to the fact that his farm comprised a portion of Chirinda Forest, a most interesting patch of residual tropical rain forest which was then quite unknown botanically, he soon took an interest in the plants of the district and sent home a large collection to the British Museum (Natural History) This was eventually worked out by various specialists, and an account of it was published in the *Journal of the Linnean Society* in 1911 The collection contained nearly 1,100 species, of which 190 were new to science, several of these were described by Swynnerton himself, including two fine new mahogany trees

Swynnerton then became interested in the problem of the significance of form and colour in Nature, and as he possessed to an unusual degree a capacity for precise and impartial observation, without any trace of that unfortunate urge to bolster up one's own theories or to smash those of other people, I suggested to him that he should undertake a really large scale experiment to test unpalatability in insects and the deductions based on it in the theory of mimicry He then began a long series of experiments lasting over five years in which very large numbers of insects of all kinds were used, the butterflies alone totalling more than 17,000 These experiments were made not only with captive animals, but also with wild birds, and were the first scientifically precise investigations in this field, and served to show the unreliability of much of the earlier work and also of criticisms based only on a few casual observations, or on the examination of the contents of birds' stomachs The mass of evidence obtained was so great that less than half of it has been published (principally in *J Linn Soc*, Zool, **33**, 203–385, 1919), though he rejected his first five hundred experiments for fear that they had not been done critically enough He demonstrated that his birds when really hungry would eat almost anything, becoming increasingly discriminative as the stomach filled, so that a graded series of preferences could be compiled with considerable accuracy

In 1918 a breakdown in health necessitated Swynnerton getting away from the worries of farming, but with his characteristic untiring energy he considered that a change of work was the best type of holiday At my suggestion he turned his critical mind to a study of the tsetse problem, for which his intimate knowledge of the fauna, flora and geology of the country specially fitted him With the assistance of the Mozambique Government he spent three months in analysing the tsetse situation in the Mossurise District of Portuguese East Africa His comprehensive report (*Bull Ent Research*, **2**, 315, 1921) contained a number of original ideas, and threw an entirely new light on the ecological aspects of the complex tsetse problem It was here that he first recommended the use of controlled grass fires as an economical method for eliminating these flies, a suggestion the value of which has been amply demonstrated in parts of Tanganyika and southern Uganda, where the vegetation was suitable for it In 1919, he became the first game warden of Tanganyika, with instructions to study the relations between game and tsetses, and in 1921 he made a preliminary survey which showed that two thirds of the Territory was infested by these flies An outbreak of human trypanosomiasis, carried by *Glossina swynnertoni*, in Mwanza district started him on the practical work of controlling the fly, and he inspired and organized the first voluntary communal effort on a large scale by the natives themselves to stop the advance of the fly by well planned clearing of bush The successful results led to a great increase in this work, and a timely visit to the country by the then Under Secretary of State for the Colonies, the Hon W Ormsby Gore (now Lord Harlech), led to official recognition of the importance of his work, so that funds were made available for its extension Nevertheless, incessant and unjustifiable difficulties were placed in his way by critics of his methods, which nearly disheartened him, but thanks to his unflagging persistence a special Department of Tsetse Research was established in 1929, and Swynnerton left the Game Department to become its first director

Here Swynnerton soon collected around him a small band of first rate scientific workers and field officers, whom he trained and inspired by his own untiring energy and enthusiasm These men have carried on a precise and intensive investigation of the ecology and habits of *Glossina* in all their complex aspects, and the work accomplished has been summarized by Swynnerton in his outstanding publication "The Tsetse Flies of East Africa", which will long be the standard work on the subject

The results obtained are such that it can now be said with some assurance that the recovery of large areas of valuable land from the tsetse fly has become economically feasible under the control of specially trained men , and it is to be hoped that the Department that Swynnerton built up will be allowed to continue its separate existence and carry on the great work for Africa which he initiated

GUY A K MARSHALL

Mr B D Burtt

THE tragic loss, through an aeroplane disaster of Mr C F M Swynnerton, Director of the Tsetse Research Department and of Mr B D Burtt botanist to the Department robs East Africa at one blow, both of a distinguished zoologist and administrator and of a field worker who had a more intimate knowledge of the vegetation of Tanganyika and probably of East Tropical Africa as a whole than any other living botanist The loss is the greater since news had just been received that the work of the Department was to be extended

Bernard Burtt was the son of Dr A H Burtt of York, who was himself a botanist Young Burtt who was born in 1902, was educated at the Friends School Ackworth, and at University College Aberystwyth, and came to Kew in 1923 He did not shine in examinations but as an all round naturalist he was outstanding Although he held a temporary post in the Kew Herbarium his real interest was in the open the living collections the local insect fauna, and the bird life in Richmond Park Later he assisted his cousin, Dr J Burtt Davy, who was preparing the first volume of his Flora of the Transvaal" Burtt's opportunity came when the tsetse fly campaign was organized The writer well remembers Swynnerton visiting the Herbarium in search of a botanist for field work in Tanganyika Burtt's services were pressed with every confidence He went out to East Africa in 1925 as District Reclamation Officer, an appointment in the Tsetse Reclamation branch of the Game Preservation Department When that branch later became the independent Department of Tsetse Research, he became the survey botanist for that Department He threw himself with all his enthusiasm into the work, the interrelationships of the fly, the game and the vegetation, and it is doubtful which of the three held the greatest attraction, for one possessed, as he was, of such intense biological interests and sporting instincts Though not the official ecologist to the Survey he became an ecologist in the widest sense At the same time he always appreciated and fostered taxonomic studies, both botanical and entomological

Burtt was an excellent collector His herbarium material was usually sufficient for a five fold distribution , a set each for Kew, the British Museum and the Imperial Forestry Institute, Oxford, a fourth and fifth set being retained in Africa for Amani and for his own Department The collections as a whole were dealt with at Kew, though specialists at South Kensington and Oxford helped in the identification of their respective groups Burtt s energies taxed the Kew staff to its utmost, one of his last sendings consisting of thirty one cases His material was always good and often represented little known or new species But though he collected many novelties they were not his first interest He was concerned with the vegetation as a whole the component species and the fly though he was quick to spot a beautiful new species as he fondly termed them He did not care for writing and published little When on leave, mountain exploration always had a strong appeal , he collected on Hanang and the Ngoro Ngoro crater and surrounding mountains besides the better known summits and he was probably the only British botanist to climb and collect on the difficult ground of the old crater of Mount Meru

Latterly Burtt travelled much by air, surveying the vegetation and the haunts of various species of tsetse fly In order to see more of Central Africa he curtailed his last leave and travelled back to Tanganyika by car with a friend by way of Nigeria, French Cameroons Belgian Congo Ituri Forest, Kivu and Uganda and of this he has left a graphic account His love of fun kindheartedness and fondness of children were evidences of a most attractive personality Always abounding in energy and good spirits, he was exactly the man for the post, and his loss will be severely felt not only by botanical institutions in Britain but very specially by the Department of Tsetse Research As a correspondent in the Territory writes I do not know how the Department will fill his place, for not only had he a unique knowledge of our country s flora but he had to an unusual extent the gift of enthusing others

A D C

THE above accounts of the loss which science in general, and East African science in particular, has sustained in the untimely deaths of Mr Swynnerton and Mr Burtt, have come from two writers who are in a far better position than I to appraise the magnitude of that loss As one who has worked for the last thirteen years under the direction of the one and in constant close association with the other, I am glad of this opportunity to add a few words about them in their capacities as leader and colleague Mr Swynnerton in addition to displaying the qualities which have been described above, so treated his staff that they one and all looked to him more as guide, philosopher and friend than as to an official superior , he was an inspiration to greater and ever greater efforts to achieve the objects for which his Department was created, and by his kindly appreciation of all efforts, even the smallest, made each feel that his contribution formed a vital part of the general scheme He never asked from anyone more than he was prepared to perform himself, and his visits to lonely workers were like an invigorating tonic, difficulties which had previously seemed insuperable disappearing, for the time at least, under his magic touch His work was inspired by a genuine love for the Africans in whose country he spent so much of his life and his treatment of them was characterized by a patriarchal attitude in the best sense of that word

Mr Swynnerton's qualities as a naturalist have been described no less than he was Mr Burtt a lover of Nature and a born observer, the great qualities of the latter in this respect, his delight in all such observations and the enthusiasm which he gave to them, all combined to make him a companion whose presence not only lightened many an arduous day under the trying conditions of the tropics, but also increased beyond measure the profits gained from such toils, to travel with him through the African forests was an education especially in the latter days as his own experience and knowledge grew His eagerness to co operate, his entire lack of selfishness, and the kindly enthusiasm with which he shared the fruits of his observations and experiences, often won at the expense of such arduous endeavour as one of lesser physical strength would have been incapable of exerting made him the most valuable of colleagues and one who inspired all with whom he came in contact with some measure of his own love of Nature This led frequently to their stimulation to attempt similar observations on their own so that his work was often extended and enriched beyond what he could have achieved alone One who was ever impatient of red tape, he found in his chief, Mr Swynnerton, a sympathetic leader under whom his natural abilities could develop and flourish in a way which would have been difficult under the more rigid and stereotyped conditions so often associated with Government service

The deaths of these two leave gaps in their Department which it will be impossible to fill entirely, their colleagues and friends suffer the bitter loss of two sources of inspiration and infectious enthusiasm which were a constant and quickening stimulus to them, the campaign against that plague of Africa—the tsetse fly—and the study of East African ecology in general both so essential to the proper development of the latent resources of that country are the poorer by the disappearance at one and the same time of an able and inspiring leader, and of a gifted and indefatigable worker who both possessed in no small degree the power to stimulate others to contribute to the subjects in which they were themselves interested and which it was their main object in life to foster

W H POTTS

WE regret to announce the following deaths

Lieut Colonel C H H Harold, O B E director of Water Examination, Metropolitan Water Board, on July 18 aged fifty three years

Miss A F Neilson lecturer in geology in the University of Glasgow on July 8

Mr F M Nelson, formerly president of the Quekett Microscopical Club and of the Royal Microscopical Society, an authority on microscopy and microscope construction, on July 20, aged eighty seven years

News and Views

Sir Gilbert Morgan, O B E, F R S

SIR GILBERT MORGAN is retiring from the directorship of the Chemical Laboratory Teddington under the Department of Scientific and Industrial Research and is taking over a directorship in another important field of work He was appointed director at Teddington in 1925 but had held previously the professorship of applied chemistry at Finsbury Technical College the professorship of applied chemistry at the Royal College of Science, Ireland, the professorship of chemistry at the University of Birmingham, as well as the post of assistant professor of chemistry in the Royal College of Science, London At Teddington, he was entrusted with the task of creating something out of nothing and was successful in establishing an institution which has become a valued national possession For this he received the honour of knighthood in 1936 Before his administrative duties limited the time which even he could find for research, Sir Gilbert published many papers in the *Journal of the Chemical Society* and other journals In fact, his invention of the word "chelate" in connexion with co ordination led his friends to name this branch of organic chemistry "Morganic Chemistry" To the Chemical Society he gave his services as editor, secretary and president, and he has been president also of the Society of Chemical Industry Sir Gilbert is one of those men who discreetly avoid giving the year of their birth in "Who's Who", but his age may be judged from the fact that he is now retiring under the usual Civil Service rules He has the good wishes of all his friends in his new appointment and they are confident that the success which has crowned all his other activities will attend his new effort Let us hope that like Chevreul, he will have a medal struck in his honour on his hundredth birthday Meanwhile, his 'chelate" personal character will continue to attract the affection and admiration of all who come into contact with him

Major F A. Freeth, O.B.E, F.R S

MAJOR F A FREETH, who has been research manager of Imperial Chemical Industries, Ltd, since the formation of the company in 1926, is retiring from that position but has consented to continue his connexion with the company in the capacity of consultant Major Freeth was educated at the University of Liverpool and at an early age gained considerable reputation as a physical chemist, becoming chief chemist to Messrs Brunner Mond and Co Ltd in 1910 On the outbreak of the Great War, he went to France with the Cheshire Regiment, but was recalled to England to undertake scientific work in connexion with the supply of munitions He rejoined Messrs Brunner Mond and for the remainder of the War he did very valuable work in developing new processes for the manufacture of explosives For his services to the country he was honoured with the O B E In 1924, Major Freeth was awarded the doctorate in the Faculty of Mathematics and Physics in the University of Leyden He was elected a fellow of the Royal Society in 1925

Mr A. G Lowndes

MR A G LOWNDES who for the past seventeen years has been a science master at Marlborough College, is retiring at the end of the present term Few science masters in public or other secondary schools devote themselves to original research, or have their contributions to knowledge published by scientific societies, but Mr Lowndes like the late Mr Edward Meyrick, who was for many years also a master at Marlborough, but on the classical side, has had a number of original contributions published in the proceedings of scientific societies and also in the columns of NATURE In 1934 he was awarded a Leverhulme research fellowship for his cinema photomicrography Immediately after the British Association meeting at Cambridge next month, Mr Lowndes is going to the Leper Settlement at Oji River, Onitsha, Southern Nigeria, as a guest of the Church Missionary Society to stay with an old pupil Dr David Money who is the medical officer in charge, and to see if useful work can be done there by a trained biologist He proposes to return to England in the spring and to work at least eighteen months at the Marine Biological Laboratory at Plymouth, where he will apply his method of finding the density of living aquatic organisms to the study of plankton

Society for the Protection of Science and Learning

MR DAVID CLEGHORN THOMSON, formerly secretary to the Oxford University Appeal Committee has been appointed general secretary, in succession to Mr Walter Adams, of the Society for the Protection of Science and Learning (formerly known as the Academic Assistance Council) which for five years has been handling the academic side of the international refugee problem Mr Cleghorn Thomson is a graduate of the Universities of Edinburgh and Oxford, a senior history exhibitioner of Balliol, he was for seven years the B B C's chief official in Scotland The Society for the Protection of Science and Learning, of which the Archbishop of York recently became president in succession to the late Lord Rutherford, acts as a central bureau of information regarding professors, lecturers and research workers displaced in their own country on account of 'race', religious or political opinions, and aids in securing the continuation of their valuable work in other countries So far, of the 1350 displaced scholars registered with this Society, 520 have been permanently placed in 38 countries, apart from more than 300 who have temporarily found work Within the last three months, the Society has received 340 applications from scholars who have had to discontinue academic activity in Austria The offices of the Society are at 6 Gordon Square, London, W C 1

Atlantic Flight with 'Pick-a-Back' Start

Mercury, the seaplane upper component of the Short Mayo composite aircraft, arrived at the airport of Boucherville near Montreal on July 21 at 12 20 p m Eastern Daylight Time, having flown from Foyne, County Limerick, in a little more than twenty hours The actual time from shore to shore, Foyne to Cape Baulewn, Newfoundland, was 13 hours 29 minutes Considerable rain and head winds were experienced during the flight, the machine arriving at Montreal with only about eighty gallons of fuel left After refuelling she took off for New York, reaching there about two hours later Captain Bennett, the pilot, and Mr Coster, the wireless operator, stated that they had experienced no unexpected difficulties during the journey, and had used their automatic pilot quite successfully as necessary The machine carried a cargo of newspapers, newsreels, and photographs principally of the royal visit to Paris The newspapers were on sale in New York on the day following their publication The successful finishing of this flight represents the completion of one of the experiments upon the problem of launching aircraft with excessive loading, due to the necessity for carrying considerable fuel and oil for long distance flights Other methods such as catapulting, topping up with fuel while in the air etc are being developed, and have been mentioned in NATURE as they have occurred

Depredations of Property by Rabbits

A BILL to protect agriculture from the ravages of rabbits was introduced in the House of Lords by Lord Sempill on July 25 It follows the lines of the report issued by the Mersey Committee on this subject, and provides powers for enabling the county councils to take action against the owner or occupier of rabbit infested land who fails to take precautions to prevent damage to neighbouring land It also provides for action for damages on the part of the aggrieved party To meet the difficulties of those who are unable to find the labour and equipment necessary for keeping down rabbits, the Bill enables county councils to provide staff and equipment for this purpose Gin traps, however, are not to be used by the staff so provided Some doubt has been expressed as to whether the destruction of rabbits by cyanide fumigation, which may now be regarded as the standard method of rabbit control, is strictly legal, and a clause of the Bill puts the use of this method for rodents beyond doubt The Bill also gives effect to the Mersey Committee's recommendation that "gin traps should in no circumstances be set in the open '

SPECIAL provision is made in the Bill for instances in which Scottish legal practice and administration differ from the English The introduction of the Bill is in the nature of a reconnaissance and has been undertaken in the hope that it may facilitate the passage next session of legislation on similar lines The promoters have a two fold objective, first to bring some relief to farmers who are suffering from the depredations of rabbits coming from neighbouring property and secondly by reducing the stock of wild rabbits in the country to reduce the amount of suffering inflicted annually by the rabbit trapping industry A leaflet written by a Bedfordshire farmer with illustrations by a Bedfordshire farm labourer has been issued in support of the Bill and copies of this together with a memorandum summarizing the details of the Bill may be obtained from ULAWS (The University of London Animal Welfare Society) 42 Torrington Square London W C 1

Prehistory and Quaternary Geology of the Sahara

THE first international meeting for the Study of the Prehistory and Quaternary Geology of the Sahara was held under the auspices of the Musée de l Homme Paris on June 27 30 Sir Robert Mond who has arranged for the publication of the results was *président d honneur* and Prof P Rivet who kindly allowed the magnificent organization of his new Museum to be used was president Archæological papers predominated at the meeting and of these the larger number dealt with the numerous and important rock drawings and rock paintings of the Desert This being the first general meeting of men of science working in different areas of almost half a continent it was more exploratory than definitive the primary purpose being to familiarize workers with progress in other parts Perhaps not least important was the opportunity for personal contact A second meeting will be held four years hence However, certain more concrete results were obtained Machinery was set up for forming a bibliography of rock paintings and drawings It was agreed that in the *pré cameline* era two clear periods of rock pictures were to be found throughout the entire area, an early level of hunters and a later one of cattle breeders Further subdivisions appear at present to be local and it also seems as if the hunters differed in different localities, whereas the cattle breeders were probably the same people throughout the Sahara Furthermore there was common accord that one *genre* of pottery is found throughout though it varies slightly locally The biggest uniform group stretches across the entire southern half and is the same as the Early *C* Group culture of Nubia and a similar culture found by the Robert Mond Expedition at Armant Its date of entry into Egypt is fixed at about 2500 B C The papers read at the meeting will be published later in full

Iron Age Site in Wiltshire

THE experiment of the Prehistoric Society in undertaking excavation on an archæological site in Wiltshire, hitherto known only from air survey, with the view of providing at the same time a training ground for young archæologists (see NATURE, July 9, p 65) has fully justified itself so far as concerns the archæological results, which, after a month's excavation, have proved of considerable interest The site selected was the lesser of two enclosures at Woodbury on the hill south of Salisbury A test excavation had shown that it had been thickly inhabited at a period definitely belonging to the Early Iron Age According to a preliminary report (*The Times*, July 20) not only did excavation confirm the existence of the pits inferred from the evidence of the air survey but it also revealed others not so indicated Further study of conditions affecting the two groups will no doubt prove of value in the future development of the technique of air photography In addition to isolated pits and post holes there is a large group of intercommunicating shallow pits appearing on the photographs as what has come to be known as the Great Dark Mark Finds included a blue bead of the Early Iron Age and quantities of Early Iron Age pottery No Romano British remains were found The pits were evidently for storage and the excavators conclude that such pits, with their vertical sides cannot be regarded as hitherto as pit dwellings The burnt material adduced as evidence of hearths, it has been shown at Woodbury by intensive study *in situ* was not formed in the pits, but was thrown into them The discovery of a similar enclosure on a hill above Harnham about a quarter of a mile away leads to the suggestion that the site now occupied by Salisbury was surrounded by a ring of such enclosures There are others at Cockey Down and north east of the aerodrome at Old Sarum The complicated nature of the site will probably necessitate a second season s excavation, although the duration of the present term of digging will depend upon the funds available towards which contributions are needed These may be addressed to the Hon Treasurer Department of British and Medieval Antiquities British Museum, Bloomsbury London W C 1

Destructive Earthquake in Greece

ON July 20 about 2 15 a m Athens was shaken by an earthquake which lasted about 10 seconds and probably had its epicentre in the Island of Eubœa (Negroponte) in the Ægean Sea The depth of focus appears to have been normal (10–15 km) and the area in which the earthquake was destructive was about 5 000 square miles Eight villages near Oropos were seriously damaged, seventeen people were killed, and about eighty injured There appears to have been some fault displacement near Halcoussie No damage appears to have been done in the capital Greece is well known to be a centre of seismic activity in historic times though of recent years the epicentres have been chiefly about 38 5 N lat, 22 5 E long which is north west of Athens Very close to the present epicentre was an earthquake which occurred on April 27, 1894, and which did damage over an area of 3 000 square miles Permanent surface movement in this 1894 shock was for thirty five miles along a well known fault parallel to the Gulf of Eubœa The ground to the north-east side of the fault was moved slightly to the north west and depressed by varying amounts from place to place, but never greater than 5 ft

Earthquakes in India

The Times correspondent from Bombay reports that several earthquake shocks have been felt daily between July 5 and July 9, with epicentres near Paliad, a town 64 miles from Bhavnagar, near the west of the Gulf of Cambay Paliad is being deserted by its population of approximately 5,000 in consequence of these shocks This area cannot be said to have been greatly affected by earthquake shocks in the past, and there is no record of one at all in Miss E F Bellamy's catalogue for the years 1913 1930 There was some destruction of property in this district at the time of the Great Cutch earthquake of June 16, 1819, which was attended by what was probably the greatest vertical surface displacement resulting from any earthquake in India The ground to the north was uplifted by 15 20 ft whilst that to the south was depressed between 10 and 15 ft When further reports come to hand, it will be interesting to see whether this epicentre is a south easterly migration of the great earthquake of more than a century ago or whether it is purely a local surface phenomenon

Science and Mankind

In his presidential address to the Society of Chemical Industry at Ottawa on June 20 on the relation of science to the world of to day, Viscount Leverhulme reminded his audience that science recognizes no political frontiers and accepts as her servants those in all countries who are engaged in the search after truth and who are working to increase mankind's knowledge of natural phenomena Discussing the relation between mankind and science, he suggested that possibly we ask too much of science and apply new methods in fields where they have only a limited application The man of science approaches all problems with the one purpose by observation, measurement and comparison to discover truth The quest is dispassionate, and though a utilitarian purpose or a commercial motive might inspire the research, that does not affect the scientific approach to the problem which characterizes the scientific worker Nearly all the contributions of science to our comfort and welfare can be traced to the quest of knowledge for its own sake

The scientist as such is not concerned with ethical and moral problems, or with the political issues which may surround developments arising from his work When, however, so many scientific discoveries having a practical application can be used destructively as well as constructively, the significance of the remark made by Lord Leverhulme's father that the greatest problem in the twentieth century would be the man behind the machine becomes apparent Lord Leverhulme, indeed, suggested that just as the ethical development of the human race has not reached the point where it can safely be given aeroplanes and high explosives, so the human mind, in the mass, has not reached the point when it can adjust itself to the new revelations of physical and astronomy If mankind is to become worthier of the gifts and opportunities science is giving him, Lord Leverhulme suggested that we must depend on forces and guiding principles at present outside the range of science Even psychology, which is giving us a deeper understanding of man's mind and emotions and behaviour has its limitations and man cannot impartially demand of science the answer to every question and expect of her the solution of every problem We should abandon the conception of science as an invading army that has ravaged and laid bare the spiritual In the daylight of true proportion and perspective science should be welcomed as a friend by those who work for the progress of humanity in other spheres of life

Science and Industry

The Messel Memorial Lecture of the Society of Chemical Industry for 1938 was delivered by Dr L H Baekeland on June 21 Dealing generally with 'Science and Industry', Dr Baekeland sketched more particularly the growth of chemical industry first in Europe and then in the United States The value of chemical industry was only fully realized in the United States with the outbreak of the Great War, and Dr Baekeland described how Mr F P Garvan's appreciation of the dependence of the United States on Germany for dyes, intermediates, photographic chemicals, medicinals, etc led him to organize the Chemical Foundation, of which he remained president until his death Any *bona fide* American chemical manufacturer or company can become a stockholder, but can only subscribe for a limited number of shares Every stockholder has the opportunity of acquiring licences by paying royalties on any patents owned by the Foundation The money thus collected is used for developing chemical education, research, and similar efforts for advancing knowledge in chemistry and for the development of chemical industries Generous support is furnished to many societies for the advancement of science and industry and medical research Garvan also recognized the possibility of much closer relations between chemical industries and agriculture, and instigated the formation of the National Farm Chemurgic Council to co ordinate agriculture, industry and science Few men, Dr Baekeland considers, had more influence in the United States on science and industry than Mr Garvan, and there is now a much wider appreciation of the importance of scientific research in industry

International Astronomical Union

The triennial conference of the International Astronomical Union, representing 27 countries, will be held at Stockholm during the week August 3–10 under the presidency of Prof E Esclangon, director of the National Observatory of Paris After the usual opening meetings, the conference breaks up into a number of committees at which astronomical problems, especially those calling for international co operation, are discussed Draft reports from no fewer than twenty nine such committees have been distributed a month in advance to those attending the meeting Among the topics to be discussed are standard notations in astronomy—a provisional list of suggested symbols has been circulated in advance—air almanacs, the publication of classical works of astronomy which are untranslated or difficult of access, the sources of error in observations with meridian telescopes and the distribution of fundamental stars for observation to different observatories, co-operation in cinematography of solar prominences to cover longer intervals of time than are available for one observatory, wave-length standards in the laboratory and the solar spectrum, the zero point of photographic magnitude and colour index, problems of stellar statistics and the absorption of light in interstellar space. Reports will be received on the present position of the "Carte du Ciel", of the observations of Eros at the opposition of 1931 and of the observations of radio signals at 71 different observatories in the world scheme of 1933. General discussions will take place in the different special committees on the past and future co-operation in the observations of stellar parallaxes, proper motions, variable stars and novæ, radial velocities, solar phenomena and cometary spectra and magnitudes.

It seems indicated from the reports that there may be discussions on such questions as the origin and maintenance of stellar energy, the hydrogen content of the sun and stars, the theory of the Fraunhofer lines, the source of the far ultra-violet solar radiation, problems of spectrophotometry (of interest to a wider circle than that of astronomers alone) and instrumental questions such as the use of the Schmidt camera, the aluminizing of mirrors and of pyrex matrices for gratings: the work of Prof. R. W. Wood on these lines suggests the ultimate replacement of prisms by gratings for stellar work. The reports of the committees give clear evidence that the conference will be helpful, stimulating and useful, and there is every reason to expect a good attendance from Europe and America. South Africa has recently rejoined the Union and will be represented. Among the less arduous features of the Congress may be mentioned visits to the Observatory at Saltsjöbaden and to the Planetarium, also an excursion to Uppsala. His Majesty the King of Sweden will give a reception at the Royal Palace. The general secretary of the Union is Prof. J. H. Oort, of the Leyden Observatory.

British Museum (Natural History): Acquisitions

The two most important additions to the Mammal Section of the Zoological Department during the present month are—the bequest by the late Mr. Norman B. Smith of his collection of Rhodesian, East African, and Sudanese game trophies, and a collection of mammals from South-west Africa presented by Major P. H. G. Powell-Cotton and Mr. Christopher Powell-Cotton. An important addition to the Osteological Section is the skeleton of a Hunter's hartebeest (*Damaliscus hunteri*) from the Tana Valley. The increasing scarcity of this species makes this specimen of special value; it is the gift of Messrs. Rowland Ward. The Museum has acquired from Lieut.-Colonel F. M. Bailey, who has just vacated the post of British envoy to the Court of Nepal, a large collection of birds made in that country. There is still much to be learnt concerning the distribution of Himalayan birds. Many species found in the Eastern parts do not occur in the Western, and the question as to how far east or west in Nepal they extend will, to a great extent, be solved when Colonel Bailey's collection has been properly examined. A further valuable selection of Swiss minerals, numbering 618 specimens from 59 carefully recorded localities, has been presented to the Department of Mineralogy by Mr. F. N. Ashcroft. The Department has purchased a large portion of the oldest meteoric stone, the fall of which is recorded. It fell in 1492 at Ensisheim, Alsace, France. For a long time the meteorite, which originally weighed 236 lb., was suspended by a chain from the vault of the choir of the parish church of Ensisheim, Alsace.

Geological Museum: Recent Acquisitions

Among the recent acquisitions of the Geological Museum is a large geological relief model of the London basin, measuring about 10 ft. by 5 ft. This is constructed on a scale of 1 in. to a mile, vertical heights being exaggerated about six times, and it includes an area extending from Foulness in the east to the Vale of White Horse in the west, and from Baldock in the north to Leith Hill in the south. The model illustrates clearly the main synclinal structure of the London basin, from the chalk rocks of which London draws so much of its water supply. Details of this structure of the solid rocks are accentuated by the colouring of drift and other surface deposits by various shades of stipple superimposed on the solid geology. A second relief model just placed on exhibition illustrates the glacial lakes of Cleveland, on a scale of 1 in. to a mile. This reconstruction, which is based on the work of the late Prof. P. F. Kendall, shows the glaciers, ice-dammed lakes, and drainage system of the Cleveland area at the time of the maximum extension of the Pleistocene ice-sheets. Among the dioramas recently added to the displays is one of an Anglo-Iranian oil-field, presented by the Anglo-Iranian Oil Co. This is the second experiment in a type of diorama in which the foreground is cut away to a depth of several thousand feet to show the geology. Two diamonds of unusual crystal form from Atian Kama, Akim, Gold Coast, have been given by Mr. G. P. Ashmore. Some five hundred varieties of marble used in decorative work in western Europe are now being exhibited.

The Science Museum

The report of the Science Museum for 1937 again directs attention to the urgent need for the rebuilding of the centre block and for the extension of the Library. Four years ago, the Advisory Council estimated that the book-stores would be filled by the end of 1938 and gave a warning that further storage room was essential. The Library is the most valuable of its kind in the country and great use is made of it by those engaged in research, and if it is to perform its functions properly it is necessary that books and periodicals should be arranged so that they can be issued to readers with the least possible delay.

It is to be hoped therefore that immediate steps will be taken to adopt the suggestions of the Advisory Council The report refers with satisfaction to the general work of the Museum and the special exhibitions which have become a feature of its activities With the advance of discovery invention and industry it is unavoidable that the collections should *increase rather rapidly* and there *is every justification* for the demolition of the old centre galleries and their re erection in keeping with the eastern block

Research on Potatoes

DURING the annual general meeting of fellows of the National Institute of Agricultural Botany at Cambridge on July 21 the chairman of the Council Dr R N Salaman reviewed the Institute s work on potatoes during the past twenty years The tests for immunity from, or susceptibility to wart disease has materially assisted the breeders efforts towards raising only immune varieties the critical examination of the many thousands of seedlings entered for these tests has led to a rapid elimination of useless varieties and the work of the Potato Synonym Committee has resulted in the almost complete elimination of synonyms The large scale demonstrations at the Potato Testing Station Ormskirk have proved that it is possible for farmers in Great Britain to grow and maintain virus free stocks for seed purposes He estimated that the loss in yield in Great Britain alone from the use of virus infected stocks *for seed purposes is in the nature of a million tons a* year With regard to potato breeding Dr Salaman thinks it very unlikely that any outstanding varieties will be produced until new methods are introduced breeding stocks require the injection of fresh blood by the use of wild tuber bearing species of *Solanum* In conclusion, Dr Salaman stressed the importance of reorganizing and regularizing potato seed production, that being the basic element in potato culture and of the utmost importance in time of war Our immediate need is a scientific organization of the industry from the production of seed at one end of the scale to the dish of potatoes on the table at the other Virus disease and blight cost the nation about five million pounds a year loss caused by the former could largely be avoided by the proper organization of the seed trade and further research might well eliminate the latter

Scientific Aspects of Refrigeration

ON July 12 a conference on Refrigeration organized by the British Association of Refrigeration was held in the rooms of the Royal Society On the previous day, meetings of the Technical Board and *Commissions of the International Institute of Re*frigeration were held at which eighteen countries were represented The first paper to the Conference was presented by Dr A K Balls of the Food Research Division, U S Bureau of Chemistry and Soils It dealt with enzyme action in food products and at low temperatures In the subsequent discussion Dr L J Harris of the Nutritional Laboratory, Cambridge, Dr Katherine Coward of the Pharmaceutical Research Laboratory and Miss M Olliver took part Prof Prescott of Boston presented a paper prepared by Messrs R R Jenkins and D K Tressler of the N Y State Agricultural Experimental Station, Geneva N Y and G A Fitzgerald of the Birdseye Laboratories U S A on vitamin C in vegetables storage temperatures for frosted vegetables Dr Kidd *of the Low Temperature Station* Cambridge, read in abstract a paper by himself and Dr Moran on atmospheric control in the preservation of food stuffs

In the afternoon the session was opened by a paper by Mr Edgar A Griffiths South Africa on the design and operation of large gas stoves Following a brief discussion on air conditioning there were three contributions from Germany Dr Plank of Karlsruhe dealt with the ideal comparison cycle of refrigeration for international use Dr F Altenkirch of Berlin read a report on an international unit of refrigeration and Dr E Schmidt of Braunschweig discussed the question of preparing standard tables for the properties of refrigerants The Conference was presided over by Dr Ezer Griffiths and Mr A R T Woods past president of the British Association of Refrigeration The papers in abstract and the discussions are being published in *Ice and Cold Storage* and other journals

Leverhulme Research Fellowships

THE following Leverhulme research scholarships among others have recently been awarded for research indicated Dr W Cule Davies (University College Cardiff) organic compounds of nitrogen phosphorus and arsenic Dr S Goldstein (University of Cambridge) turbulent motion of fluids Dr F C Happold (University of Leeds), nutrition of the three types of *C diphtheriae* in its relation to toxin production Dr M W Jepps (University of Glasgow) structure and life cycles of certain marine Protozoa Dr W H S Jones (St Catherine s College Cambridge) Greek medicine and Greek thought from 500 to 300 B C , A King (Imperial College of Science and Technology London), leader of expedition to carry out a biological, geological and physical examination of Jan Mayen Island in the Greenland Sea D A O Duffy (Bahrein Petroleum Company) lubrication problems at high pressures and temperatures , Dr O A Oeser (St Andrew s University) the combined method in the social sciences Dr G B B M Sutherland (Pembroke College, Cambridge), application of infra red spectra to structural problems in chemistry and physics , Dr W Taylor (The Polytechnic London), substitution mechanisms in aliphatic compounds , Dr B Thomas (London School of Economics and Political Science) post War migration of population within the British Empire and as between the Empire and the rest of the world Dr W H Thorpe (Jesus College Cambridge) physiology of African tropical Homoptera , R Wilson (University College Swansea), nature and position of the singularities of a function in relation to the coefficient theory of its Taylor series

The Night Sky in August

THE moon is full on August 11^d at 6^h and new on August 25^d at 11^h No star brighter than magnitude 5 3 is occulted this month Lunar conjunctions with the planets occur as follows August 12^d 7^h with Jupiter, August 16^d 5^h with Saturn, August 28^d 23^h with Venus (In New Zealand and other parts of the southern hemisphere the planet is actually occulted by the moon) Venus the disk of which is slightly gibbous, is an evening star increasing slowly in brightness to its maximum (mag -4 3) in mid October On August 31, the planet is near the first magnitude star, Spica Jupiter visible throughout the night, is in opposition on August 21 when its distance from the earth is rather less than 373 million miles Saturn, the ring system of which is fairly well open, rises about 21^h in mid August The distant planet, Uranus, now in Aries, is occulted by the moon on August 18, the occultation, however, is not visible from the British Isles, but is possible to observers in Canada On August 15, α Lyræ is on the southern meridian at 21^h 0 5^m This star together with α Cygni and α Aquilæ, make a conspicuous triangle, with the Milky Way for a background Between β and γ Lyræ, the Ring Nebula may be located with slight optical aid The variable star Algol in Perseus is coming into convenient position for observation Its variability may be observed about two hours before and after the following epochs August 18^d 2^h, 20^d 23^h, 23^d 20^h The Perseid meteors characterized by their yellowish colour, rapid flight and trains in their wake, reach a maximum about August 10 The above times are given in U T, add 1^h to convert to Summer Time

Announcements

PROF C R Harington, professor of pathological chemistry, and Prof W W C Topley, professor of bacteriology and immunology in the University of London, have been appointed members of the Medical Research Council, in succession to Prof A J Clark and Sir John Ledingham, who retire in rotation on September 30

THE following elections to the Paris Academy of Sciences have recently been made Prof T H Morgan, For Mem R S, director of the Wm G Kerckhoff Laboratories of the California Institute of Technology, Pasadena, foreign associate, in succession to the late Lord Rutherford, Prof T Levi Civita, For Mem R S, emeritus professor of mechanics in the University of Padua, foreign associate, in succession to the late Dr G E Hale, Prof E G Barrillon, professor of the theory of navigation in the Ecole d'Application du Génie Maritime, Paris, member of the Section of Geography and Navigation, in succession to the late Dr Ch Lallemand

MR J J MACGREGOR has been appointed advisory economist for the West Midland Province at the Harper Adams Agricultural College Mr MacGregor graduated in agricultural science at the University of Glasgow in 1928 and has since been continuously engaged in the study of the applications of economics to the problems of agriculture He has held appointments in agricultural economics at Seale Hayne Agricultural College and the University of Cambridge, and for the past three years has been on the staff of the Oxford branch of the Dartington Hall Economics Research Department

LIEUT COLONEL W L HARNETT, formerly professor of surgery in the Medical College, Calcutta, and recently reader in surgery at the British Postgraduate Medical School, has been appointed medical secretary to the Clinical Cancer Research Committee of the British Empire Cancer Campaign The scheme of clinical cancer research, which has already commenced, will embrace approximately seventeen thousand fresh cases of cancer annually occurring in the teaching hospitals and the specialized hospitals of the London area and the hospitals of the London County Council and the Middlesex County Council

THE Royal Astronomical Society recently decided to publish a small circular entitled *Occasional Notes*, containing short articles written in non technical style It is hoped that three or four a year will be issued, and they should prove useful to those Fellows who find the *Monthly Notices* too specialized to read with profit The first number, June, 1938, contains an account of the minor planet Hermes, discovered on October 28, 1937, and also a description of the quartz clock developed at the National Physical Laboratory, Teddington A similar clock for the Royal Observatory, Greenwich, is in process of construction

THE third International Congress for Microbiology will be held in New York City on September 2–9, 1939 It is requested that those who contemplate attending the Congress should send their names to Dr R St John Brooks, secretary of the British National Committee (Lister Institute, Chelsea Bridge Road, London, S W 1)

THE fifteenth Annual Conference of the Association of Special Libraries and Information Bureaux will be held at Lady Margaret Hall, Oxford, on September 23–26 Joint Sessions with the International Federation for Documentation will be held on September 24 and 25 Further information can be obtained from the General Secretary, Association of Special Libraries and Information Bureaux, 31 Museum Street, London, W C 1

THE Joint Committee on Materials and their Testing is organizing a meeting which will be held at the Institution of Electrical Engineers on November 25 next under the auspices of the Institution to discuss non destructive testing The subject has been divided into three sections, namely magnetic and electrical methods, X and gamma rays, acoustical and general methods Each section will be dealt with by authorities from Great Britain, the Continent and the United States The meeting will be held under the presidency of Dr A P M Fleming

ERRATUM In the inscription of Fig 1*b* in Prof Ruggles Gates' letter on "Chromosome Structure" in NATURE of July 23, page 157, the words "split satellite" written by him were, we regret, printed as "split chromosome"

Letters to the Editor

Heat Transport in Liquid Helium below 1°

EXPERIMENTS by Pickard[1], which will shortly be published, have shown that the specific heat of liquid helium becomes roughly proportional to T^3 at about 0·9°–0·8°, that is, that the anomalous part of it has died out This fact suggests that the other properties depending on the transition of atoms or groups of atoms into a state of higher energy which is responsible for the λ phenomenon—will also disappear in this region The most conspicuous property of this type is the anomalous heat conduction which has lately been investigated by various authors[2] The presumption that this anomalous conduction would vanish at very low temperatures was supported by a casual observation we found that if a capsule[3] of the type used in magnetic cooling experiments contains insufficient helium to cover the salt completely, temperature differences within the capsule equalize only very slowly. One might have expected, remembering the well-known characteristics of liquid helium II found by Rollin[4], that a film of helium would cover the salt and bring about rapid equalization of temperature

We have carried out some experiments on the heat conduction of the liquid in the following manner two containers—each holding about 1 gm of powdered iron alum—are connected by a capillary and this 'twin capsule' is filled with liquid to a level above the salt in the upper part The temperature of each part could be measured separately As the heat capacities of the salt and helium are known, we could determine the amount of heat flowing from one part to the other, if a temperature difference between them was established either by a differential heat influx from outside or deliberately by radioactive heating. We used a capillary of 18 mm length and 0·5 mm. diameter and worked with temperature differences not exceeding 0·1°. The experiments were restricted to the region between 0 2° and 0 5°, as experimental difficulties prevented us obtaining good results at higher temperatures For reasons which we shall discuss in a detailed publication, the absolute value of the temperature may be wrong by about 10 per cent. If the results are expressed in terms of a heat conductivity (κ), one obtains the following values

$T°$	κ
0 5	2 2 × 10^{-3} cal deg $^{-1}$ cm $^{-1}$ sec $^{-1}$
0 4	1 4 ,, ,, ,, ,, ,,
0·3	0·7 ,, ,, ,, ,, ,,
0 2	0·2 ,, ,, ,, ,, ,,

These values are of the order of magnitude of normal conductivities To give an idea of the times necessary for obtaining a decrease of a temperature difference to its e^{th} part in our experimental conditions, we mention that they amount to about 1, 2, 7, 50 minutes at 0·5°, 0·4°, 0·3° and 0·2° respectively. (This is in agreement with a preliminary experiment carried out with Rollin[4b] using a wider capillary and less salt; see also the remark of Shire and Allen[5].)

Our value at 0 5° is smaller by a factor 10^4 than the smallest value measured by Keesom[6], and it appears impossible to obtain Keesom's figure by extrapolating our curve This, as well as the fact that our values are nearly proportional to Pickard's 'normal' specific heats seems to justify the assumption that we are concerned here solely with 'lattice' conduction Heat conductivity can be represented quite generally[7] as the product of a specific heat, a velocity and a mean free path Assuming that in our case heat is transported by elastic waves, we can calculate from the specific heat and the velocity of sound[8] that the mean free path of these waves is of the order of 10^{-3} cm Owing to the approximate proportionality of κ and C_v, it is nearly constant in the temperature region in question, a fact suggesting that the mean free path is determined by the disturbances due to the zero point energy We shall investigate this point more quantitatively after having improved the apparatus We shall examine also at which dimensions κ begins to be dependent on the diameter of the capillary, as this would provide an independent means of determining the mean free path[9]

These results obviously imply that a rapid transport of heat by means of films will also cease at the temperatures in question (*Added in proof* experimental confirmation of this has now been obtained.) It may be mentioned that the investigation of the film phenomenon at very low temperatures has the advantage that—owing to the minute pressures of the gas—transport of heat by evaporation and recondensation is excluded. It should be noted also that our results indicate that it should be possible to employ liquid helium below 0 1°—using, of course, appropriate dimensions—in order to establish, or cancel at will, thermal contact, which is impossible in the region of anomalous conductivity This is important when working with a magnetic two-stage apparatus, as is necessary, for example, in trying to utilize nuclear paramagnetism in order to obtain still lower temperatures than can be achieved in the ordinary way

Specific Ionization of Gases by Soft Cosmic Rays Residual Currents and Deep Water Measurements

IT was shown by J Juilfs and V Masuch[1] that the ionization by cosmic rays filtered at sea level through 10 cm lead is proportional to the gas density in the measuring chamber The same property was found by us to exist in the case of the soft cosmic rays in the upper layers of the troposphere The measurements were made during a balloon ascent on May 14 between 6 km and 10 km Two similar spherical ionization chambers were used one filled with nitrogen the other with krypton containing about 5 per cent of xenon The gases were kept under 16 5 atm pressure Lindemann electrometers controlled by a Weston normal cell were employed The results are shown in Fig 1 By multiplying the ordinates of the lower nitrogen curve by the relative density of the gases 3 06 one obtains points corresponding to the krypton curve With radium C gamma rays I_{Kr}/I_{N_2} was found to be 5 3 which value differs widely from that for cosmic rays

We would emphasize once more that neither in this flight nor in the flights of March 29 1936[2] and June 18 1936 did we find discontinuities such as those found by G A Suckstorff[3] and more recently by J Juilfs[4] This is why it seems to us difficult to admit the existence in the atmosphere of radioactive substances of extra terrestrial origin Not only are our curves continuous the curve of computed mass absorption coefficients is quite smooth (Fig 2) without any maxima contrary to the results of W Kolhörster[5] Our curves are much steeper than those of Kolhorster

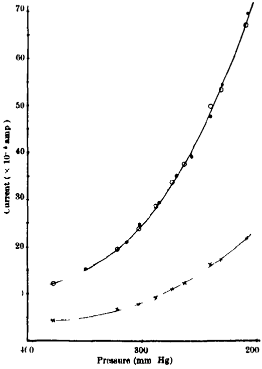

Fig 1

x NITROGEN o NITROGEN DATA × 3·06 ● KRYPTON

The residual currents of the ionization chambers were checked by us in a rock salt mine 406 m deep at Wapno (Province of Poznań) This rock salt mine is absolutely dry almost free from potassium salts and has a constant temperature of about 26° C One of the ionization chambers was filled with argon at a pressure of 30 atm It showed a residual current of about 1/320 of the value measured at earth surface Thus we had at a depth equivalent to 900 m of water a current of the same order of magnitude as that found by J Clay[6] at the deepest point (270 m) he reached in the Gulf of Aden Our residual currents showed remarkably large irregular fluctuations thus we think the anomalies found at great depths by J Clay as also those of A C Corlin[7] are not due to cosmic rays but to fluctuations of the residual currents The accidental character of these abnormalities is best seen from inspection of the ionization curves the rapid decrease of Clay s curve at 270 m being absent on the curve of Corlin

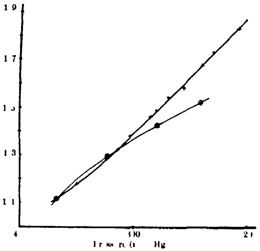

Fig 2

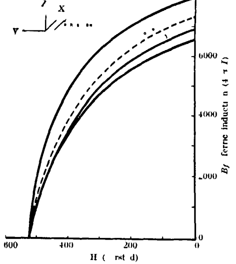
Cooling of Permanent Magnet Alloys in a Constant Magnetic Field

THE investigations of Bozorth and Dillinger[1] show that very striking increases in maximum permeability may be obtained by applying a magnetic field to high permeability nickel iron alloys during cooling So far as we are aware corresponding investigations have not been made on materials of high coercivity

We have recently carried out experiments with positive results on permanent magnet alloys of the nickel aluminium iron Mishima type by cooling in a unidirectional magnetic field from 1,200° C , and then measuring the demagnetization curves at room temperature In general, we find the coercivity is not greatly affected, but that the remanence and the value of BH_{max} are increased In the two directions at right angles, the results are practically identical with lowered values of remanence and BH_{max} Typical results for Alnico (nickel 18 aluminium 10 iron 54, cobalt 12, copper 6 per cent) are given in the accompanying graph, which refers to some experimental cubes of 4 0 cm side Care was taken to ensure that so far as possible similar thermal conditions were observed in making the control experiment



In the direction of the field the true BH_{max} value increased from 1 5 × 10^6 to 1 8 × 10^6, or 20 per cent At right angles to the field direction it dropped to 1 35 × 10^6, or 10 per cent The field strength H was 4,400 oersted If I_r represents the remanent intensity of magnetization, and I_0 the saturation intensity, at room temperature then we have found the ratio I_r/I_0 to be 0 72 in the direction of the constant applied magnetic field, 0 61 transverse to the direction of the field and 0 67 for the control with no applied field during cooling

An interpretation of these effects can be offered on lines similar to that put forward by Bozorth and Dillinger in connexion with their results On cooling a ferromagnetic below the Curie point and through the temperature range in which plastic flow occurs the magnetostrictive strains are to some extent relieved, and the actual direction of magnetization of each domain becomes an energetically favoured direction of magnetization These directions would normally be at random through the material as a whole, but if a field is applied during cooling, they will be so distributed as to favour subsequent bulk magnetization parallel or antiparallel to the direction of the original applied field In the limit, the normal six or eight equivalent easy directions for each domain (for cubic structures) would be replaced by two, and (for a particular direction) the remanent magnetization would then be equal to the saturation magnetization

This state may be nearly approached with high permeability material With permanent magnet alloys for reasons which are qualitatively clear, the effect is relatively small but it is large enough to be of possible technological value and the determination of its magnitude may contribute to a more quantitative theoretical treatment of the properties of these alloys in relation to their structure[2]

We wish to thank Prof W L Bragg for his encouragement and for suggesting following up this line of investigation and Dr E C Stoner for helpful comments

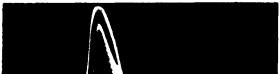
Electrical Impedance of Nerve During Activity

ALTERNATING current impedance measurements made over a wide frequency range show that the membranes of many living cells including those of several nerve fibres[1] have electrical capacities of about one microfarad per square centimetre The leakage conductance of the membranes of resting cells is small and there is considerable variation in the phase angle which is assumed to be a measure of the dielectric loss These same characteristics have been found from transverse impedance measurements made with the current flow perpendicular to the cell axis on the long single cell of the plant *Nitella*[2] and the giant nerve fibre of the stellar nerve of the squid *Loligo pealii*[3]

Because of their large diameters, it has been possible to observe and measure, in both these cells, the change in transverse impedance during the passage of the wave of excitation, which is the nerve impulse in nerve and its analogue in *Nitella* In *Nitella*[4], the membrane resistance falls from 10^4 ohm cm^2 or more to a minimum of about 500 ohm cm^2 while the membrane capacity decreases fifteen per cent with its phase angle unchanged In the squid nerve[5], the membrane resistance falls to about 100 ohm cm^2 and the capacity change is about a one per cent decrease without alteration of the phase angle

The time course of the impedance change is very similar in the two cells, although the *Nitella* is a thousand times slower For the squid fibre measurements, the amplified output of a Wheatstone bridge was applied to a cathode ray oscillograph which gave a narrow horizontal trace when the bridge was balanced and a sweep circuit moved the spot across the screen In the accompanying illustration, the nerve fibre was stimulated at one end and the band width is the record of a two per cent maximum unbalance of the bridge for a frequency of 20 kilocycles per second as the impulse came past the impedance electrodes For reference the action potential between an impedance electrode and an injured end was recorded on the same film immediately afterwards

It can be shown that the bridge unbalance is nearly proportional to the change in membrane conductance and the onset of the conductance increase here, as in *Nitella* occurs somewhat after the start of the action potential but coincides quite closely with the point of inflection on the rising phase At this point, the membrane current density reverses in direction, corresponding to a decrease of the membrane electromotive force, so that this E M F and the conductance are closely associated properties of the membrane, and their sudden changes are themselves, or are due to, the activity which is responsible for the propagation of the nerve impulse



IMPEDANCE CHANGE AND ACTION POTENTIAL OF THE SQUID GIANT NERVE FIBRE DURING THE PASSAGE OF A NERVE IMPULSE INTERVAL BETWEEN TIME MARKS AT THE BOTTOM IS ONE MILLISECOND

The capacity is probably a property of the ion impermeable aspect of the membrane, while the conductance is due to the ion permeability Since the maximum observed conductances are still far from a complete permeability and because the capacity changes are relatively slight, we have indications that the excitation does not involve a disintegration or destruction of the membrane

It is reasonable to suppose that similar changes occur in the membranes of smaller nerve fibres during excitation and the propagation of the nerve impulse

Reduction of Ions of Nickel, Cobalt, Iron and other Metals by Zinc Amalgam

THE statement that a metal will always displace any other metal below it in the potential series from solutions of its salts is well known not to be true in practice As an example the standard way of reducing ferric to ferrous ions in acid solution by zinc ought to fail because, according to the statement reduction should not stop at the ferrous stage, as it does but continue to the metal, zinc standing much higher in the potential series than iron In general it has been found that provided the displacing metal is not passive ions of metals of the *B* subgroup of the periodic classification conform to the simple statement and those of the metals iron, cobalt chromium molybdenum and other special steel metals do not Thus zinc instantly reduces to metal the ions of cadmium thallium and tin, but not those of chromium iron nickel, and cobalt, although chromium and iron are close to cadmium in the potential series, and nickel and cobalt lie below both thallium and cadmium The accepted explanation of this anomaly which preserves a belief in the potential series of metals is that with these ions the expected reaction is retarded or inhibited by causes involving the phenomena of passivity over voltage or polarization Experiments we have done seem to show however that the main cause of the anomaly lies in the existence of a protective ring of groupings around what is ordinarily regarded as the simple ion of a special steel metal

There is no doubt of the slowness of the reduction to metal of some ions In dilute sulphuric acid solution ferrous sulphate is at least a thousand times more slowly reduced by zinc amalgam than are cadmium or copper sulphate solutions under similar conditions Nickel and cobalt sulphate are from one hundred to five hundred times more slowly reduced than cadmium or copper sulphate This slowness does not seem to be primarily due to a metal surface or to the fact that the zinc is present as an amalgam or to reaction between a partially deposited metal and the electrolyte Similar differences in the rates of reduction are found when there is no metal present at all, when, for example, a solution of ter valent uranium sulphate or chloride is used This is the most powerful common reducing agent available as a solution, and reduces cadmium ions in dilute sulphuric acid instantly to metal Yet its effect on nickel and cobalt ions in dilute sulphuric acid is extremely slow, and on ferrous, divalent chromium, or ter valent titanium ions it is apparently nil

These observations suggest that the main cause of the slowness lies not in the reducing agent but in the state of the ions to be reduced This was confirmed by a number of experiments on cobalt, nickel, iron, titanium and other metal ions It was found that when nickel, cobalt or iron were in the form of complex anions, reduction to metal by zinc amalgam sometimes took place rapidly Thus from solutions containing ammonium sulphate and ammonium hydroxide in excess, nickel and cobalt are as rapidly reduced to metal by zinc amalgam as in like conditions is copper Again, from the blue solution of cobalt chloride in concentrated hydrochloric acid, where the anion is believed[1] to be $CoCl_4^-$, cobalt is reduced to metal from the moment the zinc amalgam is brought in contact with the solution (This is proved by the marked catalytic effect of metallic cobalt on the production of hydrogen from zinc and acid.) But the apparently simple cobalt ion of the pink, aqueous or dilute acid solution is not reduced when the complex anion is. As the former is believed[2] to be $Co(H_2O)_6^{++}$, it would appear that the groupings round the simple cation are the chief hindrance to the electrons which would convert the simple ion to metal atom. They guard the position which in the atom is occupied by the valency electrons. With complex anions on the other hand there is usually in equilibrium a small concentration of simple cation and this could be reduced to metal atom before it became ringed round with protective groupings.

That groupings surround the simple ions of metals like iron, cobalt, nickel, chromium, vanadium, titanium, etc., is on general grounds very probable. There is no difficulty in the reduction of any of the ions of higher state of oxidation of these metals. Quinque-, quadri- and ter-valent vanadium, for example, or ferric ion are, as is well known, easily reduced. But in these cases there are obvious vacant places inside the protected ion for the reducing electrons. It is at the final stage of reduction when the outer valency electrons have to be added that the protective effect of the groupings makes itself manifest.

From ammoniacal solutions only nickel and cobalt were found to be reduced by zinc amalgam. From strongly acid solutions, nickel, cobalt and iron may all be obtained. The other metallic ions tried—those of titanium, vanadium, chromium, molybdenum and tungsten—were found not to yield more of the metal than was sufficient to show catalytic action on the evolution of hydrogen from zinc and acid, in confirmation of earlier work[3]. In general, the nickel and cobalt combine rapidly with the zinc to form compounds containing no mercury of approximate formulæ ZnNi and ZnCo. The combination of iron with zinc occurs much more slowly. The product has the approximate formula $ZnFe_7$.

Do Anthocyanins occur in Bacteria?

IT has frequently been stated that colouring matters of anthocyanin type are produced by bacteria, and as there does not yet appear to be any justification for this view, it may be desirable to correct an error which is finding its way into the text books[1]. In most of the alleged instances of the occurrence of anthocyanins in micro-organisms, the description of the colouring matters and that of their reactions does not afford a *prima facie* case for their identification as members of the anthocyanin group and there exists no example of the isolation and characterization from such sources of a substance which is undoubtedly an anthocyanin. Two publications, however, require more serious examination.

A. E. Kriss[2] has described a pigment of *Actinomyces Waksmanii* which is red in acid, blue in alkaline solution, and in these and other respects exhibits a superficial resemblance to an anthocyanin. We have made a culture of this or a closely related organism (probably *A. violaceus ruber* Waksman), and from this have isolated in a crude form a pigment tallying in all respects with the description of Kriss. The substance is not a glucoside and undoubtedly shows considerable superficial resemblance to an anthocyanidin (for example, malvidin chloride). It is, however, definitely not an anthocyanidin, and the conclusive proof of this is that its solution in aqueous sodium hydroxide is perfectly stable and maintains a pure royal blue colour after boiling for a considerable time. No substance containing a flavylium nucleus will withstand such treatment; the heterocyclic nucleus is invariably quickly ruptured by the action of strong alkalis with the formation of orange or yellow polyhydroxychalkone derivatives.

It should be noted that the chemistry of the flavylium salts, in so far as it relates to their behaviour in acid and cold alkaline solutions, is naturally very similar to that of other classes of basic dyes such as the oxazines, thiazines and azines, which contain a suitably constituted heterocyclic nucleus associated with hydroxylated benzene rings. Thus a polyhydroxyphenazine might simulate an anthocyanidin in respect of its indicator reactions, and there is little reason to doubt that this interesting pigment of Actinomyces is derived from one of these more stable types.

It has also been claimed[3] that when *Bacillus citrulli* Sartoryi is cultured in a synthetic medium containing glucose and asparagine as sole sources of carbon and nitrogen, a triglucoside of pelargonidin is formed. The pigment was isolated and analysed and the aglucone, supposed to be pelargonidin chloride, was also analysed, the results tallying closely in both cases with those demanded by theory. Nevertheless, there are certain features of the description that suggest that this identification is erroneous and no direct comparisons were instituted; the absence of nitrogen was assumed after the failure of a qualitative test.

The object of this note is to emphasize that there is, as yet, no clearly proved case of the occurrence of anthocyanins in micro-organisms.

Œstrogenic Activity of Esters of Diethyl Stilbœstrol

IT is a well established fact that the esterification of naturally occurring œstrogenic substances such as œstrone and œstradiol causes a marked alteration in their biological activity, particularly with regard to the duration of their action. It was therefore decided to investigate the biological activity of various double esters of the synthetic œstrogenic agent diethyl stilbœstrol previously described by us[1].

The quantity of material administered was dissolved in 3 c.c. of sesame oil and given night and morning on three successive days to ovariectomized, inbred Wistar rats. Smears were taken after the third day and at intervals as long as œstrus persisted. From the accompanying table, it can be seen that esterification reduces the activity but that the effect is prolonged It would appear that the maximum prolongation without undue reduction in activity resides in the dipropionate The very great prolongation of œstrus occurring when large doses of the dimethyl ether of the compound are administered is noteworthy. The œstrus appears to be almost indefinitely prolonged

It will be observed that there is a very considerable difference between the action of double esters of œstradiol and those of diethyl stilbœstrol In the former series, maximum prolongation of œstrus occurred with the esters of the higher fatty acids[2]

Name of substance	Melting point	Quantity injected (gamma)	No of days in œstrus
Di ethyl stilbœstrol	171°	1	4
		5	4
		10	5
Di ethyl stilbœstrol di acetate	124°	1	0
		10	21
,, ,, di propionate	104°	10	50*
,, ,, di *n* butyrate	88°	10	10
,, ,, di *iso* butyrate	86–87°	10	4
,, ,, di *n* valerate	89°	10	2
,, ,, di phenyl acetate	100°	10	4
		50	30
,, ,, di benzoate	210 211°	10	0
		100	30*
,, ,, di palmitate	77 78°	50	2
		100	30*
,, ,, di-methyl ether	124°	50	2
		1000	126*
		6000	180*

* Rats still in œstrus

The esters were prepared by the action of the appropriate anhydride on diethyl stilbœstrol, usually at 100°, or by the Schotten-Baumann reaction (dibenzoate, diphenylacetate)

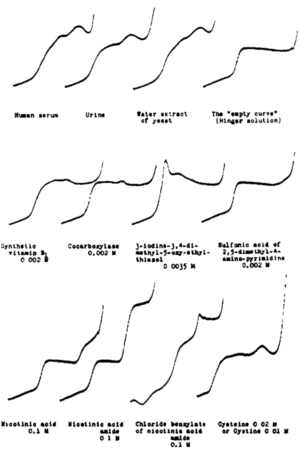
Prague Sero Reactions for Cancer

During investigations of the Prague sero reactions for cancer we have tried to identify the substances in the serum, which give the typical polarographic curve when using the technique of Brdička described in our previous letter as preparation (*b*)[1] According to Brdička[2], this curve form is characteristic for compounds of cystine, the concentration of cystine must, however, be 100–1,000 times greater than that generally found in serum (1 mgm per cent[3]), if it is to be responsible for the heights of the curve, found by Brdička and ourselves in serum Furthermore, we have found similar curves by submitting urine to the polarograph instead of serum, and we find that the concentration of cystine in normal urine is exceedingly small

The sulphur-containing glutathione and methionine are scarcely of importance, as serum gives a stronger reaction than full blood The thiazol aneurine (vitamin B_1) might be of importance, it is present in serum and urine; and a water extract of yeast was found to give curves quite similar to those from serum and urine (see accompanying graph) We therefore examined the pure components of the vitamin *B*-complex: synthetic aneurin, cocarboxylase, the thiazole part of aneurin as methylated iodide (=quaternary nitrogen), the naked thiazole part (=ternary nitrogen), the pyrimidine part of aneurine as sulpho-salt, nicotinic acid, nicotinic acid amide (=ternary nitrogen), nicotinic acid amide as benzylated chloride (quaternary nitrogen), cystine, cysteine, riboflavin (=vitamin B_2), cozymase, distilled water and Ringer solution Examples of the results are given in the graph



Polarographic curves from 0 8 v to 1 9 v

Galvanometer sensibility, 1 in 200 Concentrations are those of original solutions before preparation for polarography Concentrations in the polarographic solution (ammoniacal hexamine cobaltic chloride) are 1 . 56 of the original solutions

Serum, urine and water extract of yeast give similar curves; distilled water, Ringer solution, the ternary thiazole, riboflavon and cozymase give 'empty curves', aneurin, cocarboxylase, the quaternary thiazole, cystin, cysteine, and the nicotinic acid derivatives give curves with deviations at the same potentials as the biological fluids; but great concentrations are demanded to get curves so high as given by the biological fluids, except by the quaternary thiazole; it is not known whether this substance is present in the free state in blood and urine.

The polarographic curves in the cancer reactions must be an additive expression of the substances mentioned plus something not yet elucidated The substance must be rather stable if we may take the polarographic curve as a criterion, it can stand boiling for hours in open vessels it cannot be extracted from acid neutral or alkaline urine by shaking with chloroform benzene, petrol carbon tetrachloride, trichlorethylene or olive oil By fractional addition of methanol ethanol or acetone the substance seems to be adsorbed to the precipitates in proportion to their amounts It can be adsorbed (though not quantitatively) on fullers earth at pH 4 6 and regained by elution at pH 7 by pyridine

The substance in serum does not pass a Cellophane membrane the substance in urine passes a Cellophane membrane but very slowly

Bile (from necropsies) gives very low curve and cerebrospinal fluid (from patients) gives almost empty curves

In a recent paper Waldschmidt Leitz[4] put forward the view that the cancer substance in serum may be a sulphur free mucoid we can confirm his experiments with fractional precipitation with ethanol but our experiments with urine scarcely support the mucoid hypothesis as normal urine does not contain mucoids and mucoids do not pass 'Cellophane' membranes

We wish to thank Dr Fritz Lipmann of the Biological Institute, Carlsberg Foundation who kindly sent us some of the synthetic compounds

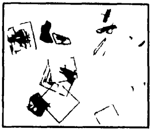
Two Active Proteins from Rattlesnake Venom

WE have found the dry venom of the Brazilian rattlesnake (*Crotalus t terrificus*) to contain about 60 per cent of a neurotoxic substance and about 10 per cent of a blood coagulating principle The latter shows all the proteolytic as well as all the coagulating activity of the crude venom It was not possible to obtain this protein in a homogeneous state or to crystallize it, but we were able to achieve in the best case a tenfold increase of activity Since the blood coagulating and the proteolytic activity was always found in the same fraction even when prepared in different ways we believe that these two activities are due to the same protein It can be obtained by saturating the venom solution to 40 per cent with ammonium sulphate whereby it is precipitated adsorbed on inactive globulins When removing the ammonium sulphate by dialysis these globulins separate out and the supernatant solution contains the coagulating substance It can be obtained as a colourless material on evaporating the water in the high vacuum after freezing We were able further to purify the coagulating principle by redissolving it in distilled water and centrifuging off the undissolved material Once it is highly purified, it shows the properties of an albumin It can also be isolated from the mother liquors of the preparation of the neurotoxic principle

This neurotoxic substance we could obtain pure and in the crystalline state as will be described elsewhere in detail[1] It is the first proteinic toxin which has so far been crystallized It contains the whole neurotoxic and the whole hæmolytic activity of the venom These two properties of many snake venoms have hitherto been attributed to two different substances one an enzyme the other a toxin This substance we called *crotoxin* (*Crotalus t terrificus toxin*) Crotoxin can be isolated from the fresh venom secretion by heat coagulation precipitation at the isoelectric point and ammonium sulphate fractionation Crotoxin crystallizes from pyridine acetate solution in thin quadratic plates which aggregate in a very characteristic manner (see accompanying illustration) Repeated recrystallization does not alter the physiological properties or the analytical data



CRYSTALLINE CROTOXIN × 96

The analysis shows crotoxin to contain 4 0 per cent of sulphur which is more than in the crude venom It has been previously shown[2] that the sulphur in all venoms investigated here is bound at least partly in the form of S S bonds and that an opening of these linkages by reduction with cysteine (—SH) inactivates the venoms just as is the case with insulin

We have therefore determined the quantitative distribution of the sulphur in crotoxin and found the following facts the cystine content of 13 2 per cent corresponds to 87 4 per cent the methionine content of 1 36 per cent to 7 3 per cent of the total sulphur The cystine value is the mean of eight determinations using the Folin Sullivan and Baernstein methods All agreed within 0 3 per cent From the methionine value which is the mean of three determinations agreeing within 0 05 per cent a minimum molecular weight of 11,000 can be calculated The molecular proportion of methionine to cystine is exactly 1 6 One is tempted to believe that the actual molecular weight will be three or six times 11 000 A molecule of the weight 33 000 would contain eighteen cystines three methionines and possibly two more sulphur containing units which, however cannot be disulphides, thiols homologues of methionine or thiolactones

Low-Voltage Electron Diffraction Tube

A SEALED OFF cathode ray tube for demonstration of electron diffraction patterns at low voltages (6,000 7,000 volts) has already been described by me[1] We have recently carried out experiments with this tube at lower voltages and have found that the electron diffraction patterns are quite visible on the fluorescent screen down to 4 000 volts and just visible down to 2 000 volts Photographic records of electron diffraction patterns could therefore be made using electrons of only 2 000 volts energy

Definition of Research Department Administration

I HAVE no desire to resuscitate or discuss law court cases in the correspondence columns of NATURE but in the summing up of a recent case which many readers of NATURE will have followed, the judge made the following statement Nobody suggested that [the plaintiff] was anything but a thoroughly perhaps exceptionally competent person in his scientific work but [the defendants] said that his incompetence lay in his failure to administer his department properly that is, to keep an eye on finance and to see that the machinery of the department was running with reasonable smoothness (*The Times*, July 22, 1938)

Quite independently of this particular law suit, and with no implication in respect of the judgment, I think that most lay readers would infer that this represents a correct and adequate definition of the duties in research department administration It will be sufficient in NATURE to mention the framing of research policies allocation of problems to the right people, co ordination, inspiration and the maintenance of a happy atmosphere as among the prime functions of the head of a department as such Moreover, the evidence in this case indicated that this extended definition was applicable to the department in question My principal point, however, is that there is a widespread tendency to regard administration as merely the supervision of office routine Any unnecessary perpetuation of this fallacy is highly injurious to efforts that are being made in connexion with administrative education which as this case so lamentably indicates, can be needed by both employers and employed

Points from Foregoing Letters

EXPERIMENTS with liquid helium at temperatures between 0 2° and 0 5° K indicate according to Dr N Kurti and Prof F Simon, that the anomalous heat conduction and probably the surface film flow vanish at these very low temperatures

Prof S Szczeniowski, Prof S Ziemecki and Dr K Narkiewicz Jodko have measured during a balloon ascent ionization by cosmic rays at heights from 6 to 10 km Nitrogen and krypton ionization chambers, each filled with gases under pressure of 16 5 atm , were used The ratio of intensities of ionization in krypton and in nitrogen is equal to the ratio of densities of these gases The curves obtained show no irregularities, which is contrary to the results of some German authors A residual current in the above chambers observed at a depth equivalent to 900 m of water shows very marked fluctuations which may help to explain the anomalies of ionization by cosmic rays at great depths found by Clay and Corlin

D A Oliver and J W Shedden find that, on cooling permanent magnet alloys of the nickel aluminium iron Mishima type in a unidirectional magnetic field, the coercivity is not greatly affected but the remanence and the value of $BH_{\max}$ are increased , they suggest an interpretation of the results

Prof K S Cole and Dr H J Curtis have shown that there is a decrease in the alternating current impedance of the giant nerve fibre of the squid during the passage of a nerve impulse Analysis of the change shows that it is due to a decrease in the membrane resistance without an appreciable change in the membrane capacity

Dr A. S. Russell and J C Carver have investigated the reduction of solutions of nickel cobalt iron and other similar metals by zinc amalgam They find that reduction to metal occurs very much more readily from complex anions of these metals than from the cations They reject the view that the slowness of reduction of the cation is primarily due to a surface action at the reducing metal, and ascribe it to the existence of protective groupings surrounding the apparently simple cations

D Erikson, Dr A E Oxford and Prof R Robinson find that the pigment of *Actinomyces Waksmanii* maintains its blue colour when boiled in alkaline solution, and cannot, therefore, be an anthocyanin No anthocyanin they state, has yet been definitely demonstrated in any bacteria

A table showing the biological activity of various double esters of the synthetic œstrogenic agent diethyl stilbœstrol is given by Prof E C Dodds, L Golberg, W Lawson and Prof R Robinson Large doses of the dimethyl ether prolong the œstrus almost indefinitely

Polarographic curves (potential changes at a dropping mercury electrode) of various substances are given by F Bergh, Dr O M Henriques and C G Wolffbrandt They conclude that the curve previously obtained with cancer serum is due to a mixture of substances One of these can be adsorbed on fuller s earth and re extracted by pyridine

A crystalline toxic protein (crotoxin) of molecular weight 11,000, or possibly 33,000, has been obtained from the venom of the rattlesnake by Prof K. H Slotta and H Fraenkel Conrat Another active constituent of this venom which has proteolytic and coagulating activity has been separated in a tenfold increased concentration

Research Items

Stone Age Correlations in South Australia

THE stone age of Kangaroo Island off the coast of South Australia has been studied by Mr Norman B Tindale (*Records S Australian Mus* 6 1 1937) with a view to its place in the mainland sequence and its relation to the stone ages of Tasmania Sumatra and Malaya In the course of a search for stone age sites on Kangaroo Island however a number of implements were found of a type differing from those of the indigenous culture which it was concluded were of Tasmanian origin and had been made between 1819 and 1836 by Tasmanian women introduced on the island by white men They belong to the later of the two phases differentiated in Tasmanian culture The Kangaroo Island stone industry includes a number of types including sumatras an elongated pebble core implement, so called here from its resemblance to an implement of the Upper Palæolithic series of Sumatra and the Malay Peninsula a discoidal flake implement resembling but distinct from the Central Australian *arapia* the horse hoof hammerstones and simple flakes Implements of the Kangaroo Island type have been found on sites on the mainland such as at Balcoracana Creek and on the old land surface at Fulham Types resembling those of Fulham have been discovered at Hallett Cove Similar implements come from Tasmania possibly from sites on which the usual Tasmanian types are not found It thus becomes evident that the Kangaroo industry belongs to an old culture having affinities with the Upper Palæolithic of Malaya A tentative correlation with the succession which has been established on the Murray River suggests that it may be similar to the culture brought to Australia from Malaya by the first native visitors and that these may have been the ancestors of the Tasmanians

People and Culture in Pukapuka

A COMPREHENSIVE study of the ethnology of Pukapuka, Cook Islands since 1914 under the administration of New Zealand, has been made by Ernest and Pearl Beaglehole, on a Bishop Museum fellowship (Bernice P Bishop Museum, Honolulu *Bull* 150, 1938) The population of the Island in 1935 was 632 In 1904 it was 435, since when it has increased consistently except in 1916, when a drop in numbers was due to the effects of a tidal wave Records for 1933 and 1934 show a total of 41 births as compared with 22 deaths Anthropometric measurements were made on 230 living and have been forwarded to Dr H Shapiro for examination The amount of racial or early inter island admixture is not great The stature for men and women is less than for other Polynesian groups Face type seems to vary between a narrow, long face with long nose and a wide face with short broad nose It is possible that analysis will reveal two physical types based on this distinction Skin colour is light brown becoming very dark on exposure to the sun Little sex differentiation is observed in motor habits Although social structure has not been much affected by cultural contacts, except in regard to the power of the chief, behaviour has been made, outwardly at least, to conform to missionary standards This gave rise to certain difficulties in the way of investigation, which however ultimately were overcome The importance of this lies in the fact that for the Pukapukan all activities led naturally to sex Whatever the purpose of a chant all came sooner or later to the fact of sex and triumphs and skill were woven harmoniously into a context that stressed the greatest joys of Pukapukan life It is important to stress the simplifications inevitably introduced by the limitations of an atoll environment This is most noticeable in material culture (witness the absence of bark cloth manufacture) but environmental influence also affects social organization Absence of kava means the non development of elaborate kava ceremonial Limitations in food resources means that much time must be spent by both men and women in procuring food There are therefore no leisured chiefs who could afford the luxury of supporting skilled artisans and craftsmen

Insect Vectors of Beet Curly Top Virus

THE relations between a virus and its insect vector are complex and but little understood at present Messrs C W Bennett and Hugh F Wallace have studied the transmission of the curly top virus of sugar beet by the leaf hopper *Eutettix tenellus* They publish some interesting and illuminating conclusions in a recent paper (*J Agric Res* 51 1 31, Jan 1938) *E tenellus* is the only vector of curly top virus in North America though other insects feed readily upon the beet plant The virus is shown to enter the bodies of all these insects but the vector species is the only one which can re infect Virus is present in the blood and the salivary glands of *E tenellus* but the available evidence suggests that no multiplication of virus takes place within the insect Experiments on transmission of the disease by fasted insects are reported The results would seem to show inactivation of the virus by one of the digestive enzymes secreted by the insect Many other findings are given and the paper opens several hopeful lines for further research

The Soybean in South Africa

DR J VILJOEN has recently published an interesting analysis of the possibilities of the soybean for South Africa (*Sci Bull* No 169, South African Dep Agric and Forestry) Pointing out the great increase in the cultivation of this bean in the United States (in 1921 the area under soybeans already exceeded three million acres representing probably the greatest change in an agricultural practice in the history of Corn Belt Agriculture) Dr Viljoen emphasizes the fact that the bean may act as a restorative crop adapted to local conditions which can be grown in rotation with maize A study was therefore made of the composition of the most important South African variety and of their expressed oils The oil proves to be nearly identical with that from the American bean Soil fertility seems to have little influence on the composition of the bean , on the other hand climatic effects are considerable, minimum temperature influencing considerably both the percentage of oil and the protein content The effects of various fertilizers upon the yield and composition of the soybean are also analysed very fully

Pasture Improvement in Australia

THE recent issue by the Australian Council for Scientific and Industrial Research of two publications (Melbourne Government Printer) dealing with different aspects of pasture improvement, illustrates the importance attached to the subject in the Commonwealth Pamphlet No 77 A Study of Persistency Productivity and Palatability in some Introduced Pasture Grasses by A McTaggart gives an account of the characteristics of some thirty four varieties or strains of grasses obtained from other countries The climatic regions of Australia vary so widely that contacts have been established all over the world on the chance of finding some strain the introduction of which would materially benefit the native pastures the northern areas in particular being in need of some such improvement The second publication (Bull 116) The Relation of Phosphate to the Development of Seeded Pasture on Podsolised Sand , is by H C Trumble and C M Donald This report discusses work forming a part of a co operative programme of investigations carried out by the Waite Agricultural Research Institute the Carnegie Corporation of New York and the Australian Council for Scientific and Industrial Research Pasture establishment in South Australia depends largely on an increase in the available phosphate content of the soil together with seeding of suitable legumes and grasses Podsolized soils due to their excessive leaching are specially low in available phosphate and nitrogen and the investigations described in the bulletin show that the dressings of superphosphate usually given should be considerably increased if the maximum economic returns of the subterranean clover pastures are to be realized 2 cwt of superphosphate per acre annually for the first three years is recommended The incorporation of grasses into the clover pastures is also discussed

Vegetative Propagation in Leafy Liverworts

W DEGENKOLBE has recently surveyed the various organs serving for vegetative reproduction in the foliose liverworts (*Annales Bryologici* **10**, 1937) Deciduous branches and thallose outgrowths are new types not previously described The author finds the type of vegetative propagation very characteristic and often of greater systematic significance than details of the perianth Gemma production is associated with leaves of a definite age and the effect on leaf production is characteristic of the type of gemma produced and upon the species In some cases, the same species may develop more than one kind of organ for propagation for example, deciduous leaves and marginal gemmæ , in some the production of deciduous leaves is periodic Vegetative propagation in this group is not antagonistic to the production of sexual organs The paper also includes a discussion of the relationship of the various types of vegetative reproductive structures to one another

Plant Pathology at Seale Hayne

THE fourteenth annual report from the Department of Plant Pathology, Seale Hayne Agricultural College, contains much useful and practical information After a general survey of the pests that occurred during the year under review on the various agricultural and horticultural crops of the district, certain problems are treated in detail Investigations have been made concerning the dwarfing disease of plants, especially polyanthus and cyclamen, from which it appears that the malformation is not necessarily associated with eelworm infestation, but that bacterial trouble may be the cause , the nature of the attack however is not yet understood The hot water treatment of narcissus bulbs for controlling eelworm is a further subject which has received much attention Although satisfactory as a method for controlling the pest damage to the flowers in the succeeding season has often occurred The temperature of the water and the time of the year at which the treatment is carried are both exceedingly important The period during which the bulbs are in a state of full dormancy is comparatively short but it is the only safe time at which to carry out hot water treatment Varieties differ considerably as to the length of this safe period and their sensitivity to hot water and the behaviour of many well known varieties is described in detail for the guidance of the grower The handling of the bulbs after treatment is also important drying on trays being preferable to sacks Further, the rate of cooling must not be too rapid, particularly in the case of bulbs treated early, or damage to the flowers will result Dry planting appears to be preferable to planting in a wet condition but if there is no storage accommodation dipping the bulbs in a fungicide after the hot water bath will reduce the likelihood of decay

A Link Between Zygomycetes and Oomycetes

THE life history of *Dicranophora fulva* a fungus belonging to the Mucorales has recently been studied by Dr C G Dobbs (*Trans Brit Mycol Soc* **21** Pts 3 and 4 167 , June 1938) This mould is of somewhat rare occurrence but has several interesting features It forms sporangia only when illuminated and zygospores only in the dark It has sexual reproduction by conjugation but the male and female gametes are recognizable structurally Contents of the male also migrate into the female gamete at fertilization there is no equal fusion as usually happens in conjugation The fungus is homothallic and female gametes may moreover, be formed without the stimulus of any opposite male *D fulva* is undoubtedly a member of the Zygomycetes where conjugation is the rule , but it is also a link between that group and the Oomycetes where a large sedentary egg is fertilized by small motile male spermatozoa

An Egyptian Mould Fungus

A MOULD fungus *Penicillium egyptiacum*, isolated from soil in Egypt is described in a recent paper by Younis S Sabet (*Trans Brit Mycol Soc* , **21**, Pts 3 and 4, 198 , June 1938) The chief characteristic of this species appears to be that it forms ascigerous fruiting bodies with readiness upon most common media Mycelium of the fungus is homothallic, and the perithecia appear under wide variations of temperature, relative acidity and atmospheric pressure, though humidity has a slight effect upon their formation The species should provide very convenient material for teaching

Soil Erosion in Tanganyika

AN interesting memorandum on soil erosion, by E Harrison, director of agriculture Tanganyika, has been issued by the Government of the Territory A representative committee appointed to advise on the problem formed the opinion that the primary method of attack should be educative rather than ameliorative, and with this end in view the already existing authorities, such as forestry, veterinary and agricultural officers, were instructed to demonstrate the serious nature of the loss caused by soil erosion and to arouse interest in the methods by which it could be checked In some districts the systems of land management evolved by the native cultivators were practically ideal counters to water erosion, but in others considerable time and patience will be required before the value of and necessity for, adopting entirely new practices is realized The relations between over stocking and soil erosion are particularly intricate The native husbandman is only capable of maintaining large numbers of cattle on land more or less denuded of persistent vegetation as otherwise he incurs the ravages of ticks, flies and worms, and these are just the conditions which accelerate soil erosion In view of this the director of the veterinary services has outlined a scheme by means of which overstocking may be relieved The chief items are expansion of a rotational grazing system, increased water supplies and the control of the type and number of stock carried, and control of grass burning Application of scientific knowledge coupled with some form of legislation is regarded as the best way of furthering the interests of the native Anti erosion rules have already been drawn up in a number of districts with considerable success

Structure of Pepsin

The cyclol structure C_2 containing 288 amino acid residues is proposed for the molecule of pepsin by D M Wrinch (*Phil Mag*, **24** 940, 1937) In this structure the mid points between adjacent atoms lie on the faces of a truncated tetrahedron which would account for the globular form of the molecule and the molecular weight of 39,200 The dimensions of unit cell in the crystal lattice as determined by X ray investigations, are *a* 67 A, *c* 462 A Taking the density as 1 32 this gives a cell molecular weight of 1,434,000 Since half the weight of the crystals is made up of water removable at room temperature, then the number of molecules per unit cell must be 1,434 000/(2 × 39 200) 18 3 X ray evidence has also suggested that the unit cell is a nine layer structure, hence there must be two molecules to each layer, each of which is associated with (say) 2 350 water molecules From the dimensions of the crystal cell, the size of the cyclol C_2 molecule and the possible arrangement of the 18 molecules in a nine layer system in the cell, it is deduced that the molecules must lie some distance apart, the distance between parallel faces of adjacent molecules being sufficiently great to suggest co ordination through the R groups of the molecules Co ordination of carboxyl groups (from the glutamic acid residues) with water molecules as intermediaries and of amide groups (from glutamine residues) are both suggested as possible The great mass of the water molecules associated with the pepsin molecules in the crystal may form mega clusters between the layers of pepsin molecules resulting in a crystalline arrangement of atoms throughout the lattice The presence of such clusters and of water molecules in the co ordination bridges would imply a collapse of the structure if the water were withdrawn and would fit with the well-known fact that pepsin crystals lose their stability on drying

Physical Investigation of Metallurgical Problems

A review dealing with the applications of magnetic determinations to the study of the structure of binary alloys of which one of the components is ferromagnetic has recently been published by W Gerlach (*Naturwiss* 26 369 1938) The problem particularly considered is that of precipitation hardening that is, the hardness of crystals formed by deposition from a supersaturated solution of one metal in another The author shows how a study of magnetization temperature curves, and coercive force temperature curves enables the phases to be analysed illustrating this by the consideration of the curves for nickel beryllium and nickel gold alloys The determination of the electrical resistance of alloys with and without the application of a magnetic field also yields results the same as those obtained by the former method Investigations of the paramagnetism and diamagnetism of alloys may also be used and Auer's work on the variation of susceptibility of a supersaturated mixed crystal system of copper and aluminium with time during which hardening is taking place at different temperatures is reviewed

T Cassiopeiæ a Temporary Reversal in its Curve

Mr F M Holborn has recently published a paper with this title (*J Brit Ast Ass* 48 8, June 1938) in which he discusses small drops in the magnitude of this star while it is on the rise Not only has Mr Holborn recorded these drops his observations have also been confirmed by others who have devoted much of their time to this subject such as Prof A A Nijland and Mr N F H Knight Mr W M Lindley a well known variable star observer, has added some remarks on Mr Holborn's paper and agrees with him that long period variables should be watched very closely for subsidiary phases and that observers should not hesitate to record such

Ellipticity of Close Binary Stars

Mr J Luyten has recently published a paper on this subject (*Mon Not Roy Astro Soc* **98** 6 April 1938) in which he attempts to estimate the degree of central condensation in close binaries from their observed ellipticities Three ellipsoidal variables are considered ζ Andromedæ b_1 Persei and π_5 Orionis the photo electric light curves of which have been determined accurately by Stebbins and Huffer spectroscopic orbital elements for the primaries have also been found If ε represent the rotation effect and φ is the ratio of the centrifugal force to gravity at the equator of the primary the values of ε/φ are found to be 45 2 7 and 7 4 respectively for the stars referred to In the case of the average star, ε/φ might be expected to be about 0 6 and the discrepancy shows the difficulty of accepting light variation as due to ellipticity of figure The paper deals also with those eclipsing binaries where estimates of the ellipticities have been made and in this case the position seems more hopeful Stars of the W Ursæ Majoris and Beta Lyræ type where the two components are almost equal in size and are revolving nearly in contact, have a mean value of 0 57 for ε/φ, indicating a central density condensation a little greater than that for the planet Saturn Many of the Algol stars utilized in the work show that the mean value of ε/φ is 0 71, corresponding to a central density concentration intermediate between Saturn and Jupiter As there are so many uncertainties involved in the computations it is impossible to say definitely what the real internal density concentration is. It may be some satisfaction to know that the results are not at variance with expectations, but beyond this it is impossible to go

Research and the Amenities of Railway Travel

WE live in an age of rapid change, due largely to the increasing readiness and rapidity with which the results of scientific progress and research are applied to the conditions of life , and, in addressing the Institute of Transport on April 11, Sir Harold Hartley showed how the amenities of railway passenger travel are being improved He confined his remarks to the aspect of the comfort of the passenger rather than to such desiderata as increased speed and safety After indicating the several conditions which together determine the comfort of a railway journey at modern speeds, he proceeded to detail the steps being taken to ensure their maximum effectiveness

Absence of vibration or irregular motion is probably the most important factor so far as the passenger's comfort is concerned, and although the difficulty of eliminating these increases greatly with increase of speed, much has been done in recent years to mitigate them Smooth running depends on the design of rolling stock and railway track and on their maintenance, and was dealt with under three aspects the motion of the wheel on the rail, the springing and coupling of the vehicles and the effect of the permanent way Over many years, a large number of experiments have been made with various designs of bogies and various conings of wheels in order to discover which type gives the best riding and the least wear, and standard practice has been based on the results

More recently a complete theoretical and experimental investigation has been carried out in the Engineering Department of the University of Cambridge by Prof C E Inglis and Dr R D Davies, as a result of which the form of the sinuous path traversed by a pair of coned wheels and their axle has been determined The results of their calculations were confirmed both in the laboratory and on the track and their theory suggests that, instead of coned wheels, cylindrical tyres should give complete immunity from lateral oscillations and 'bogie hunting' In agreement with this theory are the results of the cinematograph record taken by the Chicago, Milwaukee and North Shore Railway, which also showed that with the cylindrical wheel there was no regular oscillation and its flange rarely struck the rail Experiments in the case of the L M S train, *Coronation Scot*, with various conings and with cylindrical tyres proved the excellent riding qualities of the latter, and it was with these that the train was fitted when the record run from Euston to Crewe was made on November 16, 1936 Excessive flange wear, however, necessitated the trueing of the wheels after 20,000 miles service on the London-Glasgow run, and a compromise was then made of using a 1 in 100 coning, which gives almost as good riding at high speed without the disadvantage of excessive flange wear Another method of avoiding oscillation is to mount the wheels so as to rotate independently This eliminates 'bogie hunting', there is no sliding motion on a curve and the riding of the coach is excellent, but the construction is much more complicated and the cost correspondingly high

Coaches are also subject to oscillations due to impacts at rail joints and to other track irregularities A combination of helical and laminated springs is used to damp out these , the former give elastic support while the latter damp out the vibrations In addition, rubber is being used in seat and bed construction to eliminate vibration, the most effective material being rubber and metal or wood in alternate layers Also associated with comfortable travel is the correct balance and centring of the coaches and the correct construction of the coupling and buffing gear holding the vehicles together and preventing surging and transverse oscillation Accurate records of the riding qualities of different types of construction and of the deterioration due to wear are obtained by means of the Cambridge accelerometer which, by the movements of two weights held between stiff springs, prepares a graph of vertical and transverse oscillations and has thus helped greatly in effecting positive improvements

The maintenance of the permanent way is an important factor in ensuring the comfort of the passenger At high speeds, irregularities of the track lead to impacts which react so as to produce greater irregularity Here, the Hallade recorder is used to give a continuous record on a strip of paper of the horizontal vertical and rolling movements of the vehicle as it passes over the line and so shows where adjustment of the track is necessary The Hallade method was used in improving the track for the accelerated timings of the *Coronation Scot* and, as a result, not only had the cant of rails to be readjusted to balance the centrifugal force but also the line had in places to be slewed to improve the alignment and transition curves had to be lengthened so that the train could take the curves smoothly and without rolling at high speed On the rail joint problem, a mathematical and experimental research is being carried out at Cambridge, and its results are looked forward to with much interest, for each of these joints is a point of weakness in the track

The reduction of noise is also receiving constant attention and is being effected, so far as possible, by eliminating its production, by absorbing it at its source, by avoiding its entry to the compartment, and by absorbing quickly such noise as does enter Streamlining of coaches, welding of the track, the use of absorbent material for a top dressing on the track are some of the means in use Heating and ventilation offer opportunities for the introduction of further amenities The only satisfactory method of attaining steady conditions is by a closed system of air conditioning, but the weight and cost of the plant only justify its use in very hot and dry climates Two proprietary systems of forced air ventilation are in use on main line trains in Great Britain Indirect lighting is coming into use and the crack train of the Victorian Railways—the "Spirit of Progress"—has indirect lighting for general purposes and shoulder lights for reading

Of the improvements made in the æsthetic and general amenities the public is no doubt well aware. The more attractive external appearance of the trains, the materials and decorations used inside, the large windows, reduction of draughts, size and easy form of seats, all add to the enjoyment of the passenger, so that, in these unsettled hustling days, a long railway journey may be in some measure a comfortable relaxation and an escape from the disturbances of the world

Clines: an Auxiliary Taxonomic Principle

By Dr. Julian Huxley, F.R.S., Zoological Society, Regent's Park, London

MODERN taxonomy, after a phase of splitting, adopted the integrating principle of geographical replacement, thus uniting numerous forms previously styled species as geographical races or subspecies of a polytypic species or *Formenkreis*[1]. It seems desirable, however, to go still further in the direction of synthesis. The naming and description of subspecific forms, however necessary, is not sufficient. Further, if not supplemented by some other method, it has two actual disadvantages—it focuses undue attention on named forms as against those which remain unnamed, even when the degree of distinctness is only slightly less in the latter; it also conveys a false impression of uniformity within the named group, and thus tends to inhibit the study of intra-group regularities of variation.

Some special term seems desirable to direct attention to variation within groups, and I propose the word *cline*, meaning a gradation in measurable characters. This, being technical, seems preferable to such a term as character gradient or phrases such as 'geographical progression of characters', used by W. F. Reinig in his recent book "Elimination und Selektion". (Naturally, when it can be shown that such characters are non-genetic in origin, they will be valueless for taxonomic purposes.) Prefixes can be used to denote clines of different types: for example, ecocline, genocline (gradient in genes), geocline (geographical cline), chronocline (paleontological trend), etc. The term could be extended if desired, for example, ontocline for regular trends in individual development.

Clines may be of inter- or intra-group nature. Inter-group clines connect the mean values of the subspecies of a polytypic species (or of the species of a geographical subgenus or *Artenkreis*[1]). Numerous regularities of this sort are known, for example, the Rules of Bergmann, Gloger, Allen, etc. Rensch[1,2] has recently summarized the subject. Good examples affecting colour or size are found in many birds represented in Britain (wrens, puffins, spotted woodpeckers, bullfinches, tits, etc.). An illuminating case is that of the wrens inhabiting Fair Isle[3]. These are not sufficiently distinct to be given a separate subspecific name, but are intermediate in character as well as in position between *T. t. troglodytes* of the mainland and the Orkneys and *T. t. zetlandicus* of the Shetlands. To subsume these facts by a cline is to direct attention to a regularity that is concealed if we restrict ourselves to specification by the naming of areal groups.

Intra-group clines concern continuous variation within a population. Relatively little work has as yet been done on this laborious subject, for example, tongue length in bees[4], percentage of 'spectacled' forms in guillemots, fin rays in fish[5], pattern in lady beetles[6], vertebræ in fish[7], temperature resistance in *Drosophila*[8], etc. Sumner[9], in a coastal subspecies of deermouse (*Peromyscus*), has shown that the adaptively cryptic colour of the pelage changes gradually as one passes inland from white sand to dark soil. Still further inland there exists a distinct and much darker subspecies on very dark soil, which also shows a colour cline, though less pronounced. Where the two meet, there is a narrow zone about three miles wide where the mean colour changes very rapidly, and the variability is much higher. Off the coast, on an isolated island of white sand, lives a much paler subspecies. Here we have, first, an inter-group cline comprising three subspecies, and also intra-group ones within the two inland groups. These run in the same direction as the inter-group cline but are much less steep. These two geographical clines are separated by a very steep genetic cline (genocline) at the inter-breeding zone.

In plants, ecological clines appear to be the commonest type. Gregor[10], in *Plantago maritima*, has shown that each ecological habitat selects out a particular assemblage of genetic types, so that a regular ecocline will run from more to less saline surroundings. It is probable that similar ecoclines are to be found among land snails (Rensch[1]).

It is in no way intended that specification by clines should replace any of the current taxonomic methods. It would constitute a supplementary method which, it is suggested, would correct certain defects inherent in that of naming areal groups, notably in stressing continuity and regularity of variation as against mere distinctness of groups. It is important to note that clines for different characters may run in different directions (shrikes[11], fox sparrows[12], lincoln sparrows[13], etc.).

It would seem certain that, once attention is concentrated on this subject, regularities of intra-group variation will be found to be common—the rule rather than the exception. The correlation of these with environmental factors will undoubtedly often not be easy; and where the environmental factors vary in a complex way, the mere detection of regular phenoclines may be difficult, though not impossible[14]. However, if the study of such regularities is actively pursued, I would prophesy that we shall eventually gain a new picture of species. In many cases at least, the species will prove to consist of a population showing adaptive clines running in various directions; the continuous gradation will be broken up by various forms of isolation, which, by impeding interbreeding and the free flow of genes, will accentuate the mean adaptive differences between adjacent groups, as well as in some cases introducing non-adaptive differences[15]. The term cline is put forward as a step in this direction.

I have to make grateful acknowledgments to a number of systematists with whom I have discussed the subject, and who allow me to say that they believe that the use of the concept in taxonomy would be useful, notably Mr. M. A. C. Hinton, Mr. N. D. Riley and Mr. J. R. Norman of the British Museum (Natural History), Mr. J. S. L. Gilmour and Dr. W. B. Turrill of the Royal Botanic Gardens, Kew, Mr. B. W. Tucker of Oxford, the Rev. F. C. R. Jourdain, and the Committee on Comparative Systematics of the Association for the Study of Systematics I have also to thank Dr J Ramsbottom for suggesting *cline* as the best term to denote gradation

The Geological History of Northern Central Africa

UNTIL quite recently the interior of that vast tract of Africa which lies north of the equator and west of the Nile was virtually *terra incognita* to the geologist During the last few years however, geologists of several nationalities, particularly French and Belgian, have been actively engaged in the survey of various portions of this area As a result a considerable amount of information on the geology of the region has become available, but is scattered among numerous publications many of which are not easily accessible to British students The literature is, moreover, somewhat bewildering owing to the numerous unfamiliar stratigraphical terms which have been introduced

A well condensed and useful synthesis of existing information on this subject has recently been published by Dr K S Sandford (*Quart J Geol Soc*, 93, 534, 1937) who was attached to Major R A Bagnold s expedition in 1932 for the survey of the north western frontier of the Anglo Egyptian Sudan, and so has been able to approach the subject from the point of view of one whose own field work has taken him into almost the very centre of the area

In the geological history of this area as a whole continental conditions have prevailed over long intervals of time but three main periods are recognizable when considerable transgressions of the sea took place An Archæan basement complex of highly metamorphosed rocks is covered discordantly in most districts by pre Cambrian sediments, probably largely of marine origin Still in pre Cambrian times, these rocks were subjected to intense folding and considerably metamorphosed by pressure which came mainly from the east and west In many districts these movements were accompanied by igneous intrusion These ancient rocks, which are exposed over large areas at the present day, form the foundation of the African continent

The Lower Palæozoic was a period of marine transgression, no Cambrian rocks have been discovered anywhere in the area, but it is probable that in the Ordovician and Silurian the sea covered most of Africa north of the equator and west of the present continental watershed The occurrence of graptolites, brachiopods, calcareous algæ, and other organisms at a number of localities enables the beds to be dated with some degree of accuracy South of the great ridge joining Abyssinia to the Gulf of Guinea, however, the rocks of the Katanga System, which are at least in part marine, have yielded no fossils except obscure algal remains The dating of these rocks is, therefore, still largely a matter for dispute As shown by Dr Sandford, most workers favour the reference of at least the upper part of the succession (the Kundelungu Series) to the Palæozoic The possibility of a pre Cambrian age for the whole system cannot, however be considered to be definitely excluded Glacial tillites, absent from the Palæozoic of the more northerly region occur here at more than one horizon

Caledonian movements were mainly limited to simple elevation, so that the Palæozoic strata, in general, have remained unfolded In the central Sahara however, broad Caledonian folds have affected the Devonian beds, while in the south the beds of the Katanga System are involved in severe folding which may have occurred in Devonian times These movements resulted in the progressive exclusion of the sea in later Palæozoic times, thus inaugurating a period in which the interior of Africa was once more a vast continental region undergoing denudation

To this period belong the deposits of the Karroo System—the Lualaba and Lubilash beds of Belgian geologists—which cover wide areas in the Belgian Congo Unlike the contemporaneous beds of South and East Africa, these are poor in fossils To the north and north east the Karroo deposits pass laterally into beds classed as 'Nubian Sandstone Further information is desirable about certain beds near Guider (Léré) in the Cameroons where brachiopods (afterwards lost) are reported to have been found by O Mann associated with fish remains described by E Hennig as *Lepidotus manni* A Jurassic age has been suggested for these beds, but there is no other evidence of a marine invasion of the area in Jurassic times

In Cretaceous times, a renewed transgression of the sea took place, more restricted than that of the Palæozoic but resulting apparently, in a temporary connexion between the Tethys and what is now the Gulf of Guinea In the Eocene the sea appears to have covered much the same area as in the Upper Cretaceous although there is usually a discordance between the beds of the two periods Except marginally and very locally the sea has been excluded from the whole area in post Eocene times Alpine orogenic movements affected only the northern marginal belt of the Continent but in the interior differential movements gave rise to a series of lake basins the deposits of which, sometimes silicified, are now being recognized The Upper Tertiary was a period of much volcanic activity, which has persisted almost to Recent times

The long list of recent publications which accompanies Dr Sandford's paper should prove most useful to those seeking further information on the area

The Control of Water Supplies

THE first report of the Central Advisory Water Committee, just issued from the Ministry of Health (H M Stationery Office, 6*d* net) summarizes the conclusions arrived at by the Committee on a number of suggestions submitted to it for new legislation to facilitate the conservation and supply of water and the co ordination of water interests The most urgent of these questions, in the Committee's opinion were proposals for (*a*) the control and conservation of needed underground water resources and the protection of underground water from pollution, (*b*) the planning of water resources and supplies, and (*c*) the modernization of the existing law relating to the supply of water by local authorities and water companies

With regard to the first matter, the approved findings of a special underground water sub committee are given in which it is recommended that control should be exercised only in defined areas in which the conservation of underground water is shown, after investigation, including public inquiry to be necessary in the public interest, with the further recommendation that the Minister of Health should be empowered either on his own initiative, or on the application of any interested regional advisory water committee or person, and after consultation with the Central Advisory Water Committee, to make orders defining areas in which control of the abstraction of underground water is necessary in the public interest These with certain other recommendations relating to waste and pollution of supplies it is noted, will entail substantial amendment of the existing law under which owners have the unrestricted right to abstract water from under their land, or to allow underground resources which they have tapped to run to waste they affect also, to some extent, the powers of owners to dispose of waste matters which may cause pollution The Committee is satisfied, however as to the necessity and value of the suggested provisions

The second of the questions under consideration, namely, the planning of water resources and supplies, forms the subject of another special report by a sub committee in which it is pointed out that the regional planning of public water supplies by joint committees of water undertakers is of comparatively recent origin There are now nine regional committees in existence comprising areas with a total population of some fifteen millions Although the central committee is satisfied as to the need for regional planning by regional committees, it considers the existing procedure should be amended and that in place of voluntary assistance in their researches, the regional committees should be empowered by statute to make precepts on constituent authorities for their expenses and to obtain necessary information of consumption and resources The Minister of Health should, in the Committee's opinion be empowered to require all persons abstracting water to furnish returns of any water abstracted and not returned to the stream from which it was taken an exception being made in favour of private individuals who abstract water for their own domestic use With certain reservations in regard to details these returns should be made public to the extent of affording information in the aggregate of the quantity of water abstracted in suitable areas

The reconstitution of the regional committees is advocated in order to obtain greater efficiency, a limit of 10 members in each being considered desirable, inclusive of an independent chairman The lack of contact between water undertakers and other interests is met by the recommendation that it should be obligatory for the committees to consult all interested bodies, including catchment boards fishery boards harbour and navigation authorities and industrial users, before definite proposals are formulated in which the interests of these bodies are likely to be affected Other recommendations are made for increasing the powers of the Minister of Health in regard to the formation or alteration of joint boards and the amalgamation and acquisition of water undertakings As regards the modernization of the law relating to water supply, it is stated a consolidation bill is in course of being drafted for submission to the Minister of Health B C

The Museums Association

Annual Conference at Belfast

THE forty ninth Annual Conference of the Museums Association was held in Belfast in the week commencing July 4, and was attended by representatives of museums of all parts of Great Britain and by a number of delegates from overseas The president, Dr R E Mortimer Wheeler, announced that Her Majesty Queen Mary had graciously consented to become the patroness of the Association

In his presidential address, Dr Wheeler dealt with a number of current museum problems, and referred especially to the need for folk parks in England, and for the preservation, either there or elsewhere, of historic horse drawn vehicles which have now become obsolete

A large part of Dr Wheeler's address was concerned with air raid precautions in museums and art galleries The Museums Association has held a meeting on this subject, and has approached the Standing Commission on National Museums for advice Museum buildings may be reinforced, deep basements or country house storage may be provided for objects of primary importance, and a plan prepared for immediate action in case of emergency. Any person, Dr Wheeler said, who is directly or indirectly responsible for a museum or art gallery is neglecting an essential part of his duty if he is not taking all feasible steps to protect his collections from possible war risks

A discussion on museums and field archæology opened by Sir Cyril Fox, director of the National Museum of Wales, led to a general agreement that field work is a most important part of the training of museum officials who are in charge of archæological material Not only does it enrich the museum, but it also provides officials with personal contacts and a background of knowledge that is invaluable in the study of their own collections Curators should be given facilities to take part in excavations as an official part of their museum work In the same discussion Mr Christopher Hawkes of the British Museum directed attention to the need for a national archæological survey with centralized records

Youth in Museums was a subject of three papers by Miss Mary S Shaw, Miss C Mirèio Legge and Miss Bertha Hindshaw, all of Manchester who, from the point of view of an Egyptologist a zoologist and the curator of a children's museum, discussed the way in which museum collections could be used for vivid educational work

Mr Trevor Thomas, of the Liverpool Public Museums, read an original and stimulating paper on the æsthetics and technique of museum display—a subject which is, perhaps of little obvious concern to the scientific worker, but which is, nevertheless of the very greatest importance if museum exhibits are to appeal to the visitor whose attention is arrested by vigorous display, in which the objects are grouped and arranged in an attractive manner In this connexion, the results of experimental psychology should not be neglected

Mr Frank Pick, of the London Passenger Transport Board, gave a vigorous address on the form and purpose of a local museum, which was illustrated by many comparisons between museums in Britain and those in other countries The primary question is, he said, to whom or to what is a museum directed ? It is necessary for every museum to work to a specific aim and purpose and specialized museums are needed , for example, Britain has no museum giving a synopsis of the history and development of agriculture, nor is there one dealing with the history, meaning and purpose of clothes A museum can justify itself only as it establishes relationships with current life, and its administration is work requiring great imaginative activity

Among other papers at the Conference, Mr E Rimbault Dibdin discussed the question Are Art Galleries Obsolete ? , Mr J H Hewitt talked of the place of reproductions in the gallery , Mr A F Reeve Fowkes made a plea for a circulating national gallery, and Mr J A S Stendall described museum methods in Scandinavia A film on the work of the Royal Scottish Museum was presented by its director Mr T Rowatt

Mr S F Markham discussing the future of the museum movement in Britain made an informative and practical contribution His views will no doubt be found expressed in detail in the report on this subject which he is preparing for the Carnegie United Kingdom Trustees

About two hundred and thirty delegates attended the Conference, and were entertained by the Lord Mayor of Belfast by the Belfast Museum Committee, and by Queen's University There were excursions to the Giant's Causeway, to Armagh, and to archæological sites in Northern Ireland

Next year's Conference will be held at Cheltenham in the week commencing July 3 , it will be the jubilee of the Museums Association, and will be under the presidency of Viscount Bledisloe

International Physiological Congresses

THE sixteenth International Physiological Congress which will be held in Zurich on August 14–19, may be considered to mark the fiftieth anniversary of the first congress, which was held in the same country In honour of the occasion, F J Franklin has written a fascinating history of these congresses, which is published in *Annals of Science* (3, Part 3) It is illustrated with thirty five photographs of presidents of the congresses and others who have contributed to their success Copies are to be presented to all members

Dr Franklin gives a large number of details of the organization of these congresses which will be very useful to those responsible for congresses in the future, but he has done far more than this He has managed to catch and convey something of the enthusiastic spirit which animated the early congresses, when about a hundred keen workers met together to demonstrate experiments to one another Every effort was made to keep the arrangements as simple as possible and particular stress was laid on the importance of demonstrations There was at one time a movement in favour of abolishing other forms of communication altogether, but this was thought to be impracticable

The first congress was the result of a letter sent by the Physiological Society, London, to 109 physiologists in 1888 It met the next year in Basle, and Dr Franklin quotes interesting reminiscences of several of the eleven survivors This congress was so successful that it was decided to hold similar congresses every three years and they met successively at Liége Bern, Cambridge, Turin, Brussels, Heidelberg, Vienna and Groningen (1913) Speeches were made which emphasized the international spirit of science and it is sad to remember how this spirit was forgotten in the years of the Great War The congress in Paris in 1920 was confined to physiologists from allied countries, and the next truly international congress was held in Edinburgh three years later Since then congresses have been held in Stockholm, Boston, Rome and Leningrad The membership has grown to about 1,500 and the scientific demonstrations have tended to be overshadowed by the banquets, concerts and sight seeing expeditions which have been generously provided by the Governments of some of the countries which have acted as hosts

An attempt is being made this year to return to the simplicity of the early congresses Membership is limited to genuine physiologists and their families, and the social entertainments will be less elaborate, but physiology itself cannot be made simple again The number of communications is large, and it is still necessary to hold meetings simultaneously in five lecture rooms

The Swiss organizing committee is introducing important innovations Fifteen discussions have been organized on the kidney, the regulation of the circulation, the chemical transmission of nervous impulses, oxidation, the permeability of the skin electro physiology, steroids, fœtal respiration, nutrition, the control of respiration, the adrenal cortex, the anterior pituitary, the analysis of speech, the potential action of drugs and vitamin B_1 The contributions of the two openers of each of those discussions have already been circulated with the general programme of the meeting The opportunity *to study such documents in advance is a great boon*, but it has only been granted once before There is every reason to hope that this congress will be remembered for the high value of its scientific meetings

J H GADDUM

Beit Memorial Fellowships for Medical Research

AT a meeting of the trustees of the Beit Memorial Fellowships for Medical Research held on July 13, it was reported that F R Winton (fellow, 1927 31) had been appointed to the professorship in pharmacology in the University of London, held at University College, G R Cameron (fellow, 1930–33) to the professorship of morbid anatomy in the University of London, held at University College Hospital Medical School, A R Todd (fellow, 1935–36) to the professorship of chemistry in the University of Manchester, and that R J Kellar (fellow, 1935–37) had been appointed reader in obstetrics and gynæcology, University of London, at the British Postgraduate Medical School, London

The total number of fellowships held by full time workers during the year 1937–38 was 23 The number of candidates at the present election was higher than usual, five applied from Canada and three from Australia Fortunately, reserve funds made it possible to award more junior fellowships than are ordinarily given each year, and the election of twelve new junior fellows brought the total of those elected since the beginning of the Trust in 1910 to be exactly 200 A fresh edition has been printed this year of the 'Green Book" which summarizes briefly the after careers of fellows and their present position in research

The following elections were made, the subject and place of research being given after each name

Senior Fellowship (value £700 a year) Dr D E Green, to continue research on the role of vitamin B_1 in the oxidation of pyruvic acid, and to study a new flavin protein compound in milk (Institute of Biochemistry, University of Cambridge)

Fourth Year Fellowship (value £500 a year) Dr M H Salaman, to continue research on vaccinia and animal pox viruses (Lister Institute of Preventive Medicine, London)

Junior Fellowships (normal value £400 a year) Dr G Bourne, director of the Department of Experimental Biology, Australian Institute of Anatomy, Canberra, 1935–36 and biochemist, Commonwealth Advisory Council on Nutrition, 1937—significance of vitamin C in the endocrine system (Department of Human Anatomy, University of Oxford), Dr A L Chute, of Toronto General Hospital—experimental studies in metabolism of the brain (Department of Physiology, University College, London), Dr R O L Curry—physiology of speech disorders by photographic study of laryngeal movements (University College London), Dr J F Danielli, demonstrator in biochemistry and biophysics University College, London permeability of normal and denervated muscle to metabolic products and to drugs (Institute of Biochemistry, University of Cambridge) Dr J G Dewan, assistant physician, Toronto Psychiatric Hospital 1933 35, and since 1936 research worker at the Institute of Biochemistry, Cambridge insulin shock treatment of schizophrenia by experimental studies of brain metabolism (Institute of Biochemistry University of Cambridge), Dr Catherine O Hebb, since 1937 research assistant, Department of Physiology, McGill University—effect of thoracic sympathectomy on the activities of the lung (Department of Physiology University of Edinburgh), Dr B Katz since 1935 research worker in biophysics, University College, London—electric excitation and transmission of impulses in nerve and muscle of animals (Department of Biophysics, University College, London), J H Kellgren, resident appointment, University College Hospital, London, 1935–36, and since 1937 research worker in its Department of Clinical Research—painful conditions of the limbs and back (Department of Clinical Research, University College Hospital, University of London, Dr J J D King, house surgeon, Dundee Dental Hospital 1931 32, since 1936 research grantee of Medical Research Council—dental caries and parodontal disease (Medical School, University of Sheffield), Dr H Lehmann, research worker, Physiological Institute, Heidelberg, 1934 36, since 1936 research student of Christ's College, Cambridge—blood sugar in animals, and iron metabolism in plants (Institute of Biochemistry, University of Cambridge), W J O'Connor, resident medical officer, Adelaide Hospital, 1936, lecturer in human physiology and pharmacology, University of Adelaide, 1936 37—effect of strophanthin on the oxygen consumption of the heart (Laboratory of Pharmacology, University of Cambridge), H Scarborough, house physician, Royal Infirmary, Edinburgh, since 1934 assistant in Department of Therapeutics, University of Edinburgh—mode of destruction of vitamin C in the human body (Clinical and Chemical Laboratories, Royal Infirmary, Edinburgh)

All correspondence of fellows and candidates should be addressed to Prof T R Elliott, honorary secretary, Beit Memorial Fellowships, University College Hospital Medical School, University Street, London, W C 1

Science News a Century Ago

Faraday and Schönbein

ON July 30, 1838, Faraday wrote to Schönbein My dear Sir You know how I value your letters and may conclude that the last was very pleasant to me, though there is always a feeling of deep regret that the treasures which accompany your communications being in the German language are sealed up to me You mention Fechner s objections to my theory [of the voltaic pile] and I am exceedingly anxious to see and consider them but do not know whether they are acceptable to me or not I am very anxious to know of all important objections but I do not mind about slight ones Many have been made to me which been left to themselves have disappeared in a few months from the minds of the objectors themselves, but good and valid objections are of great importance and often I think prove the key to new discoveries Dr Poggendorff who was here lately told me of Fechner s objections but when he learnt from me that I by no means go the length of De la Rive and that I admit *many other modes of electrical excitement* besides chemical action, I thought he seemed to think that Fechner s objections were rather against De la Rive than me

Fossils of Great Britain

ON August 2, 1838, under the title Fossil Remains', *The Times* printed a petition which had been addressed to the Chancellor of the Exchequer relating to the decision not to purchase for the British Museum the two valuable collections illustrating the geology of an important portion of England formed by Mr Mansell and Mr Hawkins The petitioners stated that the collections were of peculiar value as demonstrating the subterranean structure of Great Britain, that it would be conducive to the honour and scientific reputation of England if they were placed in the British Museum, that their formation had resulted from a concurrence of rare opportunities and extraordinary qualifications in the individuals who had made them, and that if the collections were not then secured for the nation the chance of doing so might be lost for ever There were eighteen signatures to the petition, among them being those of Buckland Sedgwick Owen Murchison and Darwin

Opening of the Polytechnic Institution

ON August 2, 1838, the Polytechnic Institution, 309 Regent Street London was opened for a private view by supporters of science, and four days later it was thrown open to the public, a shilling being charged for admission The extensive building had been erected to provide reading and lecture rooms and demonstration galleries for illustrating the principles upon which every science was based, and the processes employed in arts and manufactures When ready for opening it contained a printing press, an optician s workshop, a rotatory steam engine, power looms, a diving bell, a model canal and docks, electrical and astronomical instruments, etc

Owing to financial losses the Institution was closed in 1859, but in the following year it was reopened by a new company In 1872 the classes were formed into a college which was inaugurated by the Earl of Shaftesbury In 1882 it was purchased by Quintin Hogg and opened as the Polytechnic Young Men s Christian Institute

University Events

EDINBURGH —The laureation and graduation ceremony on July 20 was also the occasion of the installation of the chancellor Lord Tweedsmuir Governor General of Canada, who had been elected by the graduates to succeed the late Sir James Barrie After conferring the honorary and ordinary degrees mainly in medicine and law the chancellor delivered his address in which he discussed the functions of a university under modern conditions In the course of this he stated The instruction of a University must be in the general principles the fundamental propositions the theory of any discipline It cannot profess to teach the practice of a profession for it cannot keep step with its rapid changes So one should regard as a *primary function* of a university the trusteeship of humane learning, the guardianship of the central culture of mankind Its task is to pursue truth by research by experiment, and by speculation and in so doing to inspire its members young and old with the love of truth, which includes the love of beauty, and with that spirit of disinterested inquiry which means intellectual freedom

Among others, the honorary degree of doctor of laws was conferred on the Right Hon Sir John Anderson, M P for the Scottish Universities, the Right Hon Walter Elliot Elliot Minister of Health Sir Alexander Gibb, the Right Hon William Shepherd Morrison Minister of Agriculture and Fisheries the Right Hon Lord Eustace Percy rector of King s College, Newcastle and pro vice chancellor University of Durham

The degree of D Sc was conferred on A D Buchanan Smith for the thesis Studies on the Inheritance of Yield and Quality of Milk in Dairy Cattle

For the first time the University awarded the degree of B Sc with honours in pharmacology which was gained with first class standing by the Earl of Suffolk and Berkshire

LONDON —The following titles have been conferred in respect of posts held at the schools of the University indicated professor of anatomy, Mr E P Stibbe (King s College), reader in clinical pathology, Dr Montague Maizels (University College Hospital Medical School), reader in demography, Dr R R Kuczynski (London School of Economics), emeritus professor of electrical engineering, Prof J T MacGregor Morris, on his retirement from the University professorship of electrical engineering at Queen Mary College, emeritus professor of organic chemistry, Prof J F Thorpe, on his retirement from the University professorship of organic chemistry at the Imperial College—Royal College of Science, emeritus professor of physical chemistry, Prof J C Philip, on his retirement from the University professorship of physical chemistry at the Imperial College—Royal College of Science

The degree of D Sc (engineering) has been conferred on Mr A G Pugsley (Battersea Polytechnic) and Mr J E P L Vigoureux (Imperial College—City and Guilds College)

SHEFFIELD —The following appointments have been made J R Grimoldby, to be demonstrator in anatomy, G E Cooke, to be assistant lecturer in civil engineering

Dr J E Smith, lecturer in zoology, has resigned

Societies and Academies

Dublin

Royal Irish Academy, June 27.

WINIFRED E. FROST · River Liffey survey (2) The food of the brown trout (*Salmo trutta*, Linn) from acid and alkaline waters. Brown trout from acid waters are usually small and slow-growing compared with those from alkaline waters Two stations were selected on the River Liffey, one Ballysmuttan acid water, the other, Straffan, alkaline water Stomach contents of 349 brown trout from Ballysmuttan and 228 from Straffan were examined Seasonal nature of the food consumed is described. Quality and quantity of different food organisms eaten are compared Some comparison of food available at the two stations is given It seems possible that the amount of food available is not responsible for difference in growth rate and size of Ballysmuttan and Straffan trout

Appointments Vacant

Applications are invited for the following appointments on or before the dates mentioned

Professor of Archæology in the University of Malta (to act also as secretary of the British Institute at Malta)—The British Council 32 Chesham Place London S W 1 (August 6)

Assistant at the Royal Aircraft Establishment South Farnborough Hants—The Chief Superintendent (August 6)

County Instructor in Poultry Keeping in the Kirton Agricultural Institute Boston Lincs —The Principal (August 10)

Lecturer in Mathematics in the University of Reading—The Registrar (August 19)

Assistant Lecturer in Mechanical Engineering in the Bradford Technical College—The Principal (August 20)

Principal of Hendon Technical College—The Secretary of the Education Committee Education Offices 10 Great George Street Westminster S W 1 (August 27)

Head of the Marine Engineering Department University College Southampton—The Registrar (August 31)

Biochemist in King s College Hospital Denmark Hill London S E 5—The House Governor (September 1)

Professor of Inorganic and Physical Chemistry in the Egyptian University Abbassia Cairo—The Dean of the Faculty of Science (September 15)

Director of the Indian Institute of Science Bangalore India The Registrar (September 15)

Senior Lecturer in Economics in the University of the Witwatersrand Johannesburg—The Secretary Office of the High Commissioner for South Africa South Africa House Trafalgar Square London W C 2 (October 1)

Lecturer in Forestry in the University of Aberdeen—The Secretary (October 31)

Physicists at the Shirley Institute (British Cotton Industry Research Association) Didsbury Manchester—The Director of Research

Lecturer in Chemical Engineering in the University of Sydney The Secretary Universities Bureau of the British Empire 88A Gower Street London W C 1

Lecturer in Geography in Raffles College Singapore—The Secretary Universities Bureau of the British Empire 88A Gower Street London W C 1

Science and a World Foundation

ON several occasions, attention has been directed in NATURE to the important work undertaken by the Committee on Science and its Social Relations, set up by the International Council of Scientific Unions, and views have been expressed upon the desirability of establishing an organization for the study of the social relations of science (see Supplement to NATURE of April 23, 1938). Briefly, the function of the former is to survey the scientific work done in certain fields, with a view to the issue at intervals of a report, with bibliography, concerning the influence of science on human society and the reaction of scientific study to the social environment, while the latter body would seek to advance knowledge on these matters by research and by the discussion and publication of papers, as well as in other ways It is generally agreed that both bodies should be careful to avoid propaganda and endeavour to be strictly impartial in the exercise of their judgment Scientific workers are rightly jealous of the high reputation they have earned for their purely objective approach to the questions they study, and it would be lamentable if any ill-considered action resulted in the devaluation of so precious a heritage.

On the other hand, men of science do not spend the whole of their lives in their laboratories They live at least as great a concern as others in the outcome of their labours, and it should be possible to satisfy these wider interests and aspirations without prejudice to the character or standard of their work. In considering the fit application of the results of their researches, especially in their bearing upon the relations between different countries, a general guiding principle has been enunciated to which the great majority of scientific workers would readily assent : that *the welfare of humanity and the interest of the whole community of nations should be placed before the narrower interests of any individual nation* Such a principle could scarcely be held to conflict with that objectivity of outlook which men of science endeavour to maintain On the contrary, to reach this ideal calls for a mental poise and freedom from bias which anyone might be proud to achieve It is certainly true to say that, whatever may have been the intentions of individuals, whether as private persons or as the representatives of their countries, its attainment has not proved easy in the past Frequently, failure has resulted from putting a lower in front of a higher loyalty, the protagonists of different Governments—and it may be doubted if any have been invariably blameless in this respect—when an important crisis has arisen, have adopted too parochial and partisan a conception of their responsibilities

This fact is brought out convincingly by Senor de Madariaga in "The World's Design", a penetrating analysis of post-War international politics. The author writes with unrivalled authority For more than six years he was head of the Disarmament Section of the League of Nations Secretariat, and later for about the same length of time he was his country's delegate to the Council, the Assembly, and the Disarmament Conference of the League The conclusion to which he came as the result of this experience is, therefore, highly significant He believes that the rivalry between nations will never be resolved until we succeed in convincing those who are in control of affairs that, whether we be Britons or Germans, Frenchmen or Italians, Americans or Japanese, we are all members of one world body, that consequently "there should be no schism in the body, but that the members should have the same care one for another The eye cannot say unto the hand, I have no need of thee And whether one member suffer all the members suffer with it, or one member be honoured, all the members rejoice with it" This surely must be the basis of the appeal made even to those who lay particular stress on the virtues of some nations and races at the expense of others, indeed the necessity to win their approval for that doctrine is the more urgent since our own good is so intimately bound up with theirs If we ourselves are driven, for the sake of petty retaliation or from a mistaken sense of what constitutes security to adopt a narrow self centred course of action we shall merely prolong and embitter the misunderstanding between nations

One aspect of an alternative and constructive policy, that relating to trade is rightly stressed in a report recently prepared by an expert committee of economists, bankers business men and others for a widely representative Conference on Peace and Economic Policies held at Washington in the spring of this year As it illustrates the trend of an important section of American opinion, an extract from it is worth quoting Urging their Government to make every effort to promote a greater interchange of goods and services between the nations generally, they say 'Trade can be called the world's most potent instrument of peaceful change Abundant trade between nations lessens the economic importance of boundaries removes most of the causes of complaint about lack of access to raw materials that can justly be made by any State on grounds of peace time needs, eases tensions over colonies in so far as those tensions are really rooted in economic grievances and are not simple matters of pride and prestige lessons the likelihood of exploitation of consumers by foreign or domestic monopolies, makes debt payments easier for debtors and more probable for creditors, facilitates thousands of everyday adjustments that in turn prevent the development of social conflict within nations and between nations" All this is sound sense, but how is the objective to be achieved ? Madariaga's proposal is that, instead of working within national environments which are inevitably influenced by national interests and outlooks, we should start from the other end, from the conception of world unity, and work back to differences in national policy, using this central conception to throw new light on the problem in hand

What part then can men of science play in hastening the desired evolution towards this world outlook in international affairs ? In the first place they can play an extremely important part by contributing to an expert and impartial survey, qualitative as well as quantitative of the world s resources in land and people raw materials and manufactured articles, buildings and technical equipment It is essential that we should begin by ascertaining these fundamental facts, if we are to seek to satisfy the basic needs of all nations and to make adequate provision for a rising standard of life notably in the more backward countries Already, much valuable research has been carried out along these lines by responsible bodies such as the League of Nations the International Labour Office the Royal Institute of International Affairs and the Institute of Pacific Relations But it is necessary to go further If such inquiries are to become really effective, they must be co ordinated, and public attention must be focused upon the conclusions reached

One example may be given to illustrate their vital importance and their possible repercussions upon events in the international sphere It is well known to men of science but not to the general public that nickel is an essential component of all steels used for armaments as well as for other purposes, and that practically the whole of the world's supply comes from a relatively small area in Canada Putting these two facts together, can we not draw the inference that it should be possible to limit the manufacture of armaments by controlling the distribution of nickel ? Surely here, actually in the hands of the British Commonwealth of Nations, is a powerful lever which has not been sufficiently explored for regulating international relations and securing peace, and unless world peace is assured, all hope of human progress and prosperity is dimmed What is true of nickel is true, in greater or less degree, of other important minerals and foods In fact the United States and the U S S R ar the only two great powers which do n customarily import large quantities of ess tial raw materials, and even they lack son commodities indispensable to normal economi life

It is for reasons such as these that the formation of a Scientific Section of Madariaga's World Foundation (see NATURE, June 18, p 1074) would be welcomed by many leading men of science A group of this character would be able to guide research into problems of world import and be a fitting medium for making the results public In this way scientific workers would have what they at present lack, opportunity for making the full weight of their collective opinion, based upon an authoritative and impartial study of the facts, felt in the councils of the nations A lead would thus be given which would no doubt be followed by other groups, drawn together, like men of science, on a functional basis It has been suggested, for example, that heads of universities and colleges might also combine to form a section of the World Foundation ; and possibly bankers and economists might form another Such a formation would have the advantage that the members of each section would know and could establish contact with distinguished workers in the same field in other countries Associated nuclei of thinking men and women would then be found throughout the world, all of whom would be contributing in their several ways to the education of public opinion directed to the same great end —the transformation of a League composed of a few nations into an effective World State

"La critique est la vie de la science"

The Grammar of Science

By Karl Pearson. (Everyman's Library, No 939) Pp xxv + 359. (London J M Dent and Sons, Ltd , 1937) 2*s* net

THE previous editions of the "Grammar of Science" were published in 1892, 1900 and 1911 They have been exhausted for a long time, but, whenever the question of a new issue was mentioned, Karl Pearson used to answer that the old text was out of date and that he was too busy with other work to undertake the necessary revision. It was never undertaken, and the present posthumous edition reproduces the chapters of the original one of 1892, using, however, their text as it was prepared for the edition of 1900

We must agree with Karl Pearson that some points in the "Grammar of Science" are out of date now. The progress in all branches of science during the forty-five years since its first appearance has been enormous, and many theories which then appeared as new are now obsolete or nearly so. Nevertheless, the book is worth preserving It sets out undying principles, and any book that does that must live The advance of science beyond where it had got when the book was written will appear far less important a hundred years hence than it does to-day, for the changes of the past forty years will have been changed. Looking back now, we see how the state of knowledge—or "belief"—in 1770 is little different from what it became in 1820, though in 1820 the difference seemed very important

But the "Grammar" does not represent any sort of text-book designed to provide information as to the actual state of science. It is just the *grammar* of science, or perhaps, of thought, and just here rests its permanent importance The purpose of the "Grammar" is indicated in the motto which is used as the title of the present article and is explained in the preface, where Pearson says, "There are periods in the growth of science when it is well to turn attention from its imposing superstructure and to carefully examine its foundations. The present book is primarily intended as a criticism of the fundamental concepts of modern science ."

The contents of the book are in harmony with the above announcement Reviewing the *principia*, the fundamental conceptions of science which were at the time either generally accepted or being introduced, Karl Pearson analysed carefully their real meaning He showed the reader how to distinguish between what is known and what is only believed in, what is a dogma and what is a generalized formula invented to put into a systematic order a number of sequences of sense-impressions Using simple examples, he explained that 'exact sciences' deal only with abstract conceptions which may or may not correspond to realities without losing their importance and usefulness For example, in physics and chemistry, we speak of electrons as of realities and probably there are realities corresponding to the concept of the electrons , however, even if there were none, nobody would deny the utility and the importance of the concept But between the world of concepts and the 'real' world of sense-impressions, there is a chasm which can be only bridged by a more or less accurate correspondence Geometry as a mathematical science deals with conceptions of planes, lines, etc. It is not concerned with dots which we may make on a sheet of paper or with the poles erected by surveyors. Still there is a correspondence—not an identity—between the two and such things as the configuration of dots and holes are the origin of geometry and also the practical part of its ultimate aim

In 1892 there was much confusion about these and similar points and as Pearson put it it was difficult to imagine anything more hopelessly illogical than the statements with regard to force and matter current in elementary textbooks Later on in 1900 Pearson recorded a considerable improvement and expressed the hope that the science of the future while agnostic as to the supersensuous will replace *knowledge* by *belief* in the perceptual sphere and reserve the term *knowledge* for the conceptual sphere—the region of their own concepts and ideas—of ether atom organic corpuscle and vital force—of physical and plasmic mechanics

There is no doubt that Karl Pearson s hope is by now fulfilled in many quarters For example the opinion that geometry is concerned with discovering the properties of a really existing space would probably be generally considered to day as very naive Yet the clarification of ideas about science has not affected all its branches to the same extent Paradoxically enough the very branch which was recently developed largely under the direct influence and inspiration of Karl Pearson himself is not in a very satisfactory situation I mean of course mathematical statistics Before Karl Pearson it could scarcely be considered as an independent science Since his writings however a great number of authors all over the world have been attracted by the subject and to day statistical literature concerned both with the theory and with its applications is enormous

Repeating the usual phases of development of all mathematical sciences mathematical statistics started with solving various particular problems having in view some immediate practical application One can easily understand the enthusiasm of the authors discovering more and yet more distant fields where their results could be usefully applied But this enthusiasm and the rapid and in many respects brilliant development of mathematical statistics could not escape certain dangers The rapidity of the development in width so to speak was associated with a much slower process in depth When reaching some result promising an important practical application the authors did not care to make much effort to put it into precise terms distinguishing clearly the conceptual and perceptual spheres of thought or to give satisfactory mathematical proofs

At the early stages such an attitude was understandable forgivable and probably even useful But it has established bad habits It is only in exceptional cases that present day authors think of distinguishing between what they have to say about observable facts and the conclusions deducible from postulates The two spheres are usually mixed

It would be easy to illustrate this but any example of importance and its subsequent discussion would take more space than an article like the present can afford to give It is therefore hoped to illustrate the problem in more detail elsewhere But to indicate what I have in mind I may quote a minor misunderstanding contained in a short passage from an important article published recently Unimportant as the example is it provides a remarkable illustration of the confusion of the perceptual and the conceptual spheres of thought The normal or Gaussian law of error rests partly on a particular hypothesis about the nature of error that the error of any individual observation is the resultant of a large number of comparable and independent components and partly on comparison with frequencies in actual series of observations Both arguments are defective If the Gaussian law rests on some hypothesis or other then these words are meant to denote merely some mathematical theorem But then any comparison with the results of actual experiments would be irrelevant On the other hand if the law is meant as a description of some observational facts then it could not rest on a hypothesis

Even when authors write on what purports to be the mathematical theory of statistics they do not aim at the accuracy of proof and presentation to which we have been accustomed in other branches of mathematics for many generations Lack of clear and systematically arranged definitions (for example some authors prefer to arrange them in alphabetical order !) makes it difficult for one statistician to understand another and their *knowledge* being mixed with *beliefs* they frequently engage in acute and fruitless disputes Unusual passages to the limit integration term by term of divergent series hidden and inadmissible differentiations under the sign of the integral are very common and the theorems purported to be rigorously demonstrated prove to be inapplicable in this that and some other particular case

To put it shortly it seems to me that with mathematical statistics we are to day in a period when it is well to turn attention from its imposing superstructure and to carefully examine its foundations The whole body of statistical knowledge should be revised and criticized including of course the work of Karl Pearson himself That statistical literature of the present day contains a considerable amount of criticism in general and of Karl Pearson in particular is true But this criticism is of a specific kind What is wanted is not attacks on particular authors but a dispassionate and constructive review of the whole body of our knowledge of mathematical statistics Owing to the work of the French School and of such writers as A Kolmogoroff and H Cramér the theory of probability is already on a proper level Similarly we have good expositions of the elements of statistical theory such as books by W P Elderton and by G Udny Yule and M G Kendall covering roughly what was thoroughly worked out either by Karl Pearson himself or by what may be called the first team of workers inspired by him Now is the time to set to work so that we may put in order what has been done of recent years to apply in fact to mathematical statistics the principles that Karl Pearson applied in the Grammar of Science to science generally By reminding us of these principles the new edition of the Grammar should do much to create among the theoretical statisticians the necessary critical spirit

J NEYMAN

Structure, Properties and Uses of Timber

(1) Timber
its Structure and Properties By H E Desch Pp xxi + 169 + 27 plates (London Macmillan and Co Ltd 1938) 12s *6d* net

(2) Timber Drying and the Behaviour of Seasoned Timber in Use
By R G Bateson Pp xiv + 138 + 7 plates (London Crosby Lockwood and Son Ltd 1938) 10*s* *6d* net

(3) Wood Preservation
By George M Hunt and Prof George A Garratt Pp ix + 457 (New York and London McGraw Hill Book Co Inc 1938) 30s

(4) Timber Products and Industries
the Harvesting Conversion and Marketing of Materials other than Lumber including the Principal Derivatives and Extractives By Prof Nelson Courtlandt Brown Pp xviii + 316 (New York John Wiley and Sons Inc London Chapman and Hall Ltd 1937) 17*s* *6d* net

THERE have recently appeared four manuals two published in Great Britain and the other two in the United States which deal with wood and its technical properties which with the exception of timber mechanics cover most of the available knowledge on the subject

(1) Desch has attempted to assemble all available information and in so doing has rendered a service as the literature available on the subject is at present scattered through many reports bulletins, records and pamphlets issued by research organizations and individuals

The author has divided his subject into four parts, dealing first with the structure of timber followed by a short treatise on its gross features Part 3 discusses the properties of wood, basing the information largely on investigations carried out in more recent years both in Great Britain and in the United States Seasoning of timber is dealt with under the heading Considerations influencing the Utilization of Timber the subject matter is good and it might more suitably have found place in Part 3 The book runs for 169 pages with ninety good illustrations The work is the first of its kind and should be useful

(2) Bateson s book is a complete treatise on the subject and is a welcome addition to the literature on timber technology especially as it incorporates all the most recent results of research The book opens with a discussion on the necessity of seasoning timber before use followed by a detailed description of what takes place as the wood loses its moisture which discussions lead on to methods of air and kiln seasoning

It is noticeable the practical way in which the author has approached his subject always keeping in mind the many difficulties the operator may encounter especially in kiln seasoning As an example may be cited the inclusion of drying schedules to assist those dealing with the more common timbers in use in Great Britain The descriptions of various types of drying kilns is fully gone into as also control instruments The chapter dealing with prevention of splitting and warping is instructive and it is shown how these defects may be greatly minimized by a little fore thought and expense The book ends with an engaging chapter on the future of seasoning timber in Great Britain in which the author is perhaps over sanguine as to extension of kiln seasoning The work is well illustrated and contains 131 pages of letterpress

(3) Wood Preservation , by Hunt and Garratt is a work of mark as might be expected from two authors with such wide experience As a text book it should admirably fulfil its object which is stated to be for the use of forest and engineering schools and for those employed in treating and using processed timber All factors governing antiseptic

treatment of timber are dealt with primarily referring to the industry in the United States while from the text it is very apparent that much of the data given and facts recorded are from observations made and results obtained in the laboratory and field by the authors themselves

The problems involved in wood preservation are discussed and two chapters are devoted to deterioration of wood which is estimated to amount in the United States to fifty million pounds sterling annually Both in Great Britain as in America and the Continent many hundreds of wood preservatives have been tried in the last eighty years but coal tar creosote and its derivatives may be said still to hold the day though latterly in the United States and in India creosote has been mixed with petroleum oils primarily with the object of reducing costs Much stress is laid by the authors on seasoning timber before treatment—and rightly so

The processes of treating timber are described but nothing very strikingly new is recorded Probably the most original part of the work is the chapter dealing with the economic aspect of preserving timber The end is a treatise on fire retarding treatment of wood in which it is stated that the industry has not developed rapidly in the States The book is of 457 pages and is illustrated by clear photographs and figures

(4) In Timber Products and Industries by N C Brown it is stated that the object is twofold to give in detail the many uses and processes of manufacture of wood in the United States and throughout to stress ways and means of reducing waste The author argues—and rightly so—that by grouping several wood working industries in the vicinity of large forests intense utilization of the crop may be ensured

The book is divided into seven parts commencing with constructional material and going on to chemically derived products—an interesting chapter In describing in great detail the naval stores industry which is the largest in the world and located in the Southern States the author continually uses the term gum for resin which would appear to be the common term used in the United States though curiously incorrect In connexion with this industry it would appear that by far the greatest quantity of resin is distilled in direct fired stills whereas in France and in India the process of distillation is carried out under vacuum in steam stills no doubt due to the fact that the resins contain higher boiling point oils The chapters dealing with mechanically reduced products and wood fuel charcoal briquetting and wood gas are of interest and worth study

The work covering 316 pages is extensively illustrated though the plates are in some cases neither clear nor sharp R S P

Current Physics

The Physical Society
Reports on Progress in Physics Vol 4 General Editor Allan Ferguson Pp vi + 389 (London The Physical Society 1938) *20s* net

A RAPIDLY changing science such as physics sets a difficult task to those attempting classifications or the preparation of annual reports Favoured classifications may be almost as numerous as the classifiers In any one year the amount of new results published in each of the main divisions of physics varies considerably Most of the results fit into one of two classes

In the larger class a physical constant or group of constants which has already been determined for n substances is determined for the $n+1$th substance These research papers are easy to classify to abstract and to tabulate It may well be doubted whether an ordered story of this kind of research helps either the research worker or the scholar The data are more readily accessible if presented in tables or in such a scheme as the card index system of the Science Museum library What is new in type in this class of researches is usually a matter rather of technique than of result

In the second type of research new properties of substances already examined by older methods are studied by placing the substance in a new environment where it is subjected to new physical conditions These researches are much fewer and are far more difficult to abstract to classify or to deal with in reports There can be little doubt however that all would wish to see them in annual reports both for their intrinsic interest and for the relevance of their results to work in progress

In this fourth annual volume of the Physical Society s reports the editor Prof Allan Ferguson explains in a preface the aims and objects of the reports The original suggestion was that each annual report would cover the main branches of physics and that one or two articles dealing with prior developments in some special subject would be included The policy of the Society is not however, fixed and immutable and the present volume shows a welcome increase in the number and extent of these special articles dealing with subjects as widely varying as the measurement of time supersonics in relation to molecular constitution refrigeration the application of Fourier series methods to molecular structures and the diamagnetic and paramagnetic anisotropy of crystals

There is in most of the sections a welcome unbending by the writers of even the most highly technical articles in that the standard terms of their subject are carefully explained For example on pp 339–40 Dr J M Robertson explains the term structure factor before dealing with the most complex crystal structure determinations

Biological factors are gradually receiving recognition and study in physics chiefly in applied physics They are unavoidable in musical acoustics and Dr F G Richardson in his general article on sound includes a section called conventionally Subjective Aspects containing reference to work on aural flicker In refrigeration the biological properties of food to be stored are briefly discussed by Dr Ezer Griffiths Mr W H Ward deals with electrical oscillation and biological materials

In all these subjects the relevance of biological properties of the material studied is readily apparent It is less apparent in general physics where its recognition might help clarity For example the observer is referred to in two quite different articles In a fascinating article on the measurement of time the Astronomer Royal has much to tell of the use of the eye and ear and of observations made by different observers Although he starts in astronomical style by stating that The measurement of time depends fundamentally upon the rotation of the earth on its axis it is clear from the subsequent discussion that he might equally well have started in biological style by declaring that The measurement of time like every other measurement depends fundamentally upon human judgment of coincidence The research worker is usually satisfied to take his time from standard time signals clocks and tuning forks Dr Spencer Jones here gives a clear and concise account of what has to be done by the astronomer to give these trustworthy standards The essential part played by the human observer is quite definitely stated

The second article referring to the 'observer' seems to leave the reader in some doubt as to the nature of the observer In his article on the beginnings of the new quantum theory Dr H T Flint explains that the behaviour of particles may be studied by means of the wave equation Reference is then made to observers When observers have made experiments and eliminated their own vagaries and those of their apparatus, they will come to the conclusion that in particular circumstances they have been able to locate a particle By using coincidence observation experimental physicists can locate tiny drops of oil in the Millikan experiment or of water in a Wilson cloud chamber or tiny fragments of sulphur in a Brownian motion experiment But none of these tiny objects is a particle They each have dimensions On p 166 it is stated that If we wish to locate a particle by any optical method as accurately as we can we illuminate it with very short wave length and look at or photograph the object using a microscope to help us Apart from the reference to a particle this statement suggests laboratory operations carried out by human observers

The Astronomer Royal leaves us in no doubt that he is writing about human observers with eyes ears hands and even initials (p 6) Dr Flint s exposition leaves the relationship if any, of his observers to the type discussed by the Astronomer Royal in considerable doubt

In general character the volume is similar to the *Reviews of Modern Physics* but with a wider scope than any one volume of the American publication The most striking omission is an index A classified annotated analysis of the year s physics books compiled from the monthly lists given in NATURE might be very helpful to those physicists who cannot use the larger libraries

At the end of his preface Prof Allan Ferguson for once seems to give up a little of his broad mindedness in order to warn reviewers against discussing co ordination in such work as the preparation of annual reports Nor is it a matter for grave concern if an article on recent advances in nuclear physics appears simultaneously with an article having the same title and published under the auspices of say the Zetetic Society Must scientific workers then like politicians wait until a matter is one for grave concern before doing anything about it ? If so they may at least deeply deplore the lack of co ordination In any case the present reports are published primarily in the interests of the Fellows of the Society Yet co ordination of the essential but non creative part of scientific work is surely in the interests of the members of any society The jovial personality of the present editor could secure co operative effort if it were humanly possible We may hope, therefore that in a future preface he will tell something of the avenues explored and the stones turned in the effort to secure co operation

W H GEORGE

Cryptogamic Botany

Vol 1 Algæ and Fungi By Gilbert M Smith Pp viii+545 24s Vol 2 Bryophytes and Pteridophytes By Gilbert M Smith Pp vii+380 18s (McGraw Hill Publications in the Botanical Sciences) (New York and London McGraw Hill Book Co Inc , 1938)

THESE two volumes together form a good general review of the Cryptogams in which representative series in each of the major groups are described in detail Though most of the types chosen are those found in the United States the majority are so very widespread that students who adopt these books for their reading in cyptogamic morphology need not necessarily be confined to the United States Thus, the work should be welcomed by British students, since though the major groups of Cryptogams are well reviewed in separate British text books, there are few satisfactory single works which cover all representative Cryptogams

Vol 1 opens with a discussion of the classification of spore producing plants The author gives cogent reasons for not recognizing the Thallophyta as a division of the plant Kingdom, but prefers to split the Algæ into several distinct divisions He also gives reasons for considering the Fungi as having evolved from Protozoa rather than Algæ, and therefore keeps them apart Following this discussion are descriptions of various types of Algæ Fungi, Fungi Imperfecti and Lichens

Vol 2 considers the Bryophyta and Pteridophyta The Bryophyta are considered in the evolutionary series—Hepaticæ, Anthocerotæ and Musci , thus the author follows Howe's suggestion that the Anthocerotæ (consisting of a single order—Anthocerotales) be placed in a special class co ordinate with the other two The Pteridophyta are divided into the more generally accepted classes—Psilophytinæ Lycopodinæ Equisetinæ and Filicinæ

These two volumes can be warmly recommended to students of cryptogamic botany In themselves, there is enough material for students reading for a general degree, whereas for the benefit of honours degree students and research workers there are about two thousand references

The Petrology of the Sedimentary Rocks

By Dr F H Hatch and Dr R H Rastall Third edition, revised by Maurice Black (Text Book of Petrology, Vol 2) Pp iv+383 (London George Allen and Unwin Ltd 1938) 15s net

MUCH research on problems connected with the sedimentary rocks has been carried out since the publication of the last edition of Hatch and Rastall's text book, in 1923 The appearance of a revised edition is therefore timely The author and subject bibliographies with which the latest edition is provided reveal the extent of the literature on sediments, and it is noteworthy that a very considerable proportion of the papers cited have been issued during the last fifteen years The task of revision, which has been carried out by Mr M. Black, must therefore have been no light one Actually a great deal of the text has been re written and the general arrangement of the subject matter has been modified Apart from the incorporation of new material, an important change is the omission of the chapters on metamorphism These, it is claimed would now be superfluous, owing to the publication recently of Dr A Harkers' book ' Metamorphism On the other hand, Mr T Crook's useful appendix on the minerals met with in the loose detrital sediments, which was excluded from the second edition has been re introduced in modified form

Mr Black has carried out his task very thoroughly and few omissions of any importance were noted It is perhaps to be regretted that a substance of such economic importance and scientific interest as bauxite should not have received fuller treatment and it is rather surprising that no reference is made to the limestone deposits known as cornstones that are so well known in Britain These, however, are minor blemishes in what is, to all intents and purposes, an entirely new text book, filling a definite gap in British geological literature Both Mr Black and the publishers are to be congratulated on its preparation

Rainfall and Tree Growth in the Great Basin

By Ernst Antevs (American Geographical Society, Special Publication No 21) Pp v+97+2 plates (Washington Carnegie Institution , New York American Geographical Society, 1938) n p

IN recent years drought has become a major problem in the western States, and it is important to study the variations of rainfall over as long a period as possible In this region there are few rainfall stations with long records—scarcely any before 1871—and the author accordingly set out to supplement these with data from other sources, such as historical records of rains and droughts, crops, the levels of lakes and rivers and especially the annual growth rings of trees

The area studied includes a number of lake systems in the Great Basin, mainly in Oregon, northern California, Nevada and Utah Each area is discussed in considerable detail and the results are expressed in curves and tabulations back to about 1850, with curves of tree growth permitting general estimates for longer periods The results of this detailed study are then combined in a summary of the major fluctuations of rainfall since 1801, from which the author draws some hopeful inferences as to a future improvement in the water supply In order to find a parallel to the drought of 1924–34, he has to go back to the 1840's Since 1887 there have been nearly three complete minor oscillations, but it is doubtful if these are truly periodic, and the predictions of water supply based on them are to that extent uncertain The final chapters give the curves of tree growth back to 1450 and discuss their significance

The book is a most interesting study of historical climatology, bringing together and interpreting several different lines of evidence in a sound and critical way

The Application of Moving Axes Methods to the Geometry of Curves and Surfaces

By Dr. G S. Mahajani. Pp vii+60 (Poona Aryabhushan Press, 1937). n p

APPARENTLY Routh was the first to turn to account the fact that the curvature and torsion of a space curve represent the components of rotation of the fundamental axes as they move along the curve. It was Darboux, however, who developed fully this application of kinematics

In the tract under notice, Dr Mahajani, employing vectors, derives a compact and manageable notation for the equations of relative motion The Serret-Freult formulæ form a special case, in the author's notation

$$\frac{d}{ds}(l_1, l_2, l_3) = \begin{vmatrix} l_1, l_2, l_3 \\ -\tau, \theta, \kappa \end{vmatrix},$$

where obviously the symbol on the right is to be read in a special manner. By assigning appropriate motions to the representative point, he succeeds in outlining much of the material discussed by means of these formulæ in the usual introductory course, including some results in the theory of curves on surfaces

The essay shows that, at any rate within the limits which its author has set himself, the method can be an elegant one. It may well appeal to those who find that their need of the subject is not continuous enough to enable them to memorize completely the calculus of the unit vectors *t*, *n*, *b*. A clearer exposition than Dr Mahajani's could not be wished for

Observationes Anatomicae Selectiores:

Amstelodamensium 1667–1673. Edited with an Introduction by F J. Cole. Pp. xi+45+59+4 plates (Reading: Prof F J Cole, University, 1938.) n p.

THIS beautiful little book, of which not more than a hundred copies are to be printed for sale, emanates from the Department of Fine Arts of the University of Reading, and represents a faithful reprint with the preservation of all grammatical, typographical and engraver's errors of two little tracts of the Private College of Amsterdam, copies of which in Great Britain were hitherto only to be found in the British Museum, the University of Glasgow and the Bodleian libraries In his excellent introduction, Prof. F. J. Cole states that these tracts are the rarest and least known of all the early literature of comparative anatomy The first tract printed at Amsterdam in 1667 contains notes on the anatomy of the calf, horse, bullock, sheep, swan, duck and dove, and the vivisection of a dog and frog, while the second tract published in 1673 deals mainly with the pancreas of fishes such as the sturgeon, herring, cod, turbot, pike, perch and trout. Of special interest to the biologist are the descriptions of injection of the branchial artery of a calf with mercury, the air sacs of the swan, duck and pigeon, the palatal organ of the carp, the swim bladder and pneumatic duct of the carp, pike and herring, and the ligamentous spiral valve or 'skrew gut' of the sturgeon.

Civilization and Disease

By Dr C P Donnison Pp xv+222. (London: Baillière, Tindall and Cox, 1937) 10*s* 6*d*

THE author, whose work is based on his experience as medical officer in charge of a native reserve in Kenya as well as in private practice in England, maintains that in a small but important number of diseases which can be divided into two groups a relationship can be traced between civilization and the disease The first group comprises four diseases, namely, high blood pressure, diabetes mellitus, exophthalmic goitre and peptic ulcer, while the second group consists of functional disorders usually known as psychoneuroses High pressure, it is shown, is rare in primitive races and its incidence increases with development in towns and with education, while it is common in the African in America and very prevalent in Europe and the United States The same holds good with regard to diabetes mellitus, exophthalmic goitre, peptic ulcer and psychoneuroses In other diseases, according to the author, there seems to be some relationship with civilization, but the evidence is too inadequate to justify any definite conclusions

Primitive Races of To-day

By J W Page Pp 348. (London George G Harrap and Co, Ltd, 1938) 8*s* 6*d* net.

ANTHROPOLOGISTS may cavil at Mr Page's use of the term 'primitive' as applied to existing peoples of the simpler cultures; but they will not quarrel with the acumen with which he has chosen his authorities, nor the ability with which he has singled out for mention the significant details in the various modes of life and their relation to environment, in these accounts of typical examples of food gatherers, hunters, cultivators and nomadic herdsmen The peoples whom he has elected to describe range in distribution from polar snows to the tropical forests of the equator and the islands of the Pacific Not all still exist to-day as described here, and others, as Mr Page notes, have long been diminishing in numbers, while rapid changes in culture are universal.

Mr Page's illustrations are well chosen, and his sketch maps, rough as they are, useful.

Applied Mycology and Bacteriology

By L D Galloway and Dr R. Burgess. (Modern Chemical Industries Series) Pp ix+186. (London. Leonard Hill, Ltd, 1937) 10*s*

THIS little book fills the need for a simple introduction to the study and control of bacteria and fungi. The treatment given herein is lucid, comprehensive and accurate The book may be cordially recommended, therefore, to those, such as chemists and others, having interests in the supervision of foods, water, textiles and perishable goods generally, who wish to obtain some understanding of the agents of decay and how to circumvent them. Even the specializing microbiologist can learn of developments outside his own sphere. Production is good, and misprints are all but absent. H. N.

Fundamental Aspects of Erosion

By Dr. E. G. Richardson, King's College, Newcastle-on-Tyne

EROSION is a problem of considerable complexity which cannot readily be expressed in terms of known physical laws Up to the present, it has lain mainly in the sphere of the engineer, who has evolved a number of empirical laws for predicting its magnitude It is evident by the disagreement not merely in coefficients but even in the functions on which the erosion is made to depend, that these rules are designed only to fit the conditions which fall within the experience of particular engineers and have no universal application Before further progress can be made in combating the evil, one must attempt to reduce the problem to its simplest proportions

Pioneer fundamental research in the subject was carried out by Gilbert in 1914 in America, while recently Hjulstrom[*] in Sweden and I myself[†] in Great Britain have independently carried out laboratory and field experiments in which the question has been studied under conditions which reduce the variable quantities to a minimum The factors which then remain can be grouped under two headings first, those which concern the eroding stream—whether it is in steady motion or turbulent and in particular the value of the gradient of stream velocity at the surface of the soil , secondly, the nature of the soil bed, the size, shape and density of the grains and whether they are closely or loosely compacted.

In field experiments, all these factors intervene in a fashion which does not allow of the separation of their respective contributions It is desirable, as a basis for establishing the laws of erosion, to make experiments first in artificial channels, using a bed of loosely compacted and nearly homogeneous particles so that the factors just enumerated can be varied one at a time. Measurements are then made of the mean quantity of silt transported at various heights above the bed and of the gradient of mean velocity transverse to the stream in the same vertical section I have made such observations in a glass-sided channel having a wooden floor on which a bed of sand, graded within fine limits by sieving, was laid The velocity of the stream along the channel was measured from point to point by a hot-wire anemometer, while the silt concentration at any level was measured photo-electrically in terms of the absorption which a narrow beam of light cast athwart the stream suffered in virtue of the intervening sand carried in suspension Although the experiments were actually carried out in water, there is no essential difference between the behaviour of air and water in this respect, due regard being paid to their relative viscosities and to the relative buoyancies of the eroded material in the two media

The disturbing influence on the soil which lifts the grains into the stream is in the main due to the shear on it, that is, the product of viscosity and the velocity gradient at the bed, while the restoring force is determined by the natural rate of sinking of the grains Under the combined action of erosion and gravitational force, the grains are so distributed that the silt concentration at any level fluctuates about a mean the value of which falls off exponentially with height, at least over the major part of any vertical section. If the bed be changed for one of coarser but still homogeneous particles, the exponent in this relation and with it the total quantity of silt carried in suspension diminishes in consequence of the faster rate of free fall of such particles If then one plots the height against the logarithm of the silt concentration, a line is obtained which is almost straight (except near the bed) and the slope of which can be taken as a measure of the erosion coefficient For a given velocity gradient, provided the stream is sufficiently turbulent to afford adequate mixing, this coefficient is found to be inversely as the grain size, bearing out theory in this respect

Similar considerations apply in natural streams, where the bed, of course, is not homogeneous. Samples taken out of the River Tyne in flood at various depths and analysed in respect of size-frequency give a series of curves the mean slope of which for each size follows the same law Occasionally it is reported by hydraulic engineers (who measure in terms of surface velocity and slope of bed) that 'colloidal' particles are less easily eroded than somewhat larger ones, so that in a mixed bed there is maximum rate of erosion occurring for a diameter round about one tenth of a millimetre. This anomaly is usually attributed to the superior cohesion which a clay sludge possesses. The exception, however, disappears if one reckons erosion in terms of the velocity gradient instead of surface velocity for it is well known that the distribution of velocity across a stream carrying finely divided or colloidal material is not the same as that in homogeneous fluids or in those in which large crumbs of sparsely distributed soil are in suspension

---

[*] *Bull Geol Inst Uppsala*, **25**, 221 (1935) This paper contains a bibliography of erosion Other more recent accounts of (gross) silt transport will be found in *Water Pollution Research, Tech Paper* No. 7 (1937), *U.S Waterways Expt Stat. Paper* No 17; *U S Geol. Survey Water Supply Paper* No 797; Y L Chang, *Proc Amer Soc Civ Eng*, Nov (1937).

[†] *Phil. Mag.*, **17**, 769 (1934), *Proc. Roy Soc*, A, **160**, 583 (1937).

The extent to which the soil allows the fluid to permeate it has probably the most important influence in loosening the bed prior to actual erosion When water passes over the soil a certain amount of chemical action may take place particularly when the surface soil is a limestone formation but whether this occurs or not once the water is able to break up the soil into smaller crumbs or to encircle those which already existed before its passage it can exert pressure to move the formerly coherent grains which then become potential silt Sometimes an actual lifting force may be exerted that is to say the line of action of the pressure may be inclined upwards instead of along the bed This happens notably when a grain is lying a little higher than its fellows on the bed and its foundations are partially or completely undermined by the fluid The local velocity at the top of the grain is then greater than that beneath so that the force towards the underside may exceed the total of gravity and the downward force on the top Such a state of affairs often occurs where a pebble is resting on a sandy bottom and the resultant force may lift it momentarily into the body of the stream As soon however as it has risen above the boundary layer of fluid in which the major part of the gradient of velocity is found the lift is lost and it sinks back

This accounts for the series of long hops by which the heavier particles follow the stream and the ultimate formation of ridges or dunes but this process does not in my observation contribute markedly to the silt load of the stream itself which is a function merely of the degree of turbulence velocity gradient and grain size Penetration of the soil by the eroding fluid can nevertheless change the distribution of velocity near the bed—in fact at a sandy bottom the gradient of velocity may show a point of inflection separating the domain of quasi fluid motion above and quasi solid flow below—and in this way react on the silt load carried in suspension

How, then, do the means commonly adopted for the prevention of erosion stand in the light of these results ? Attempts to lower the overall slope of the land by farming on the terrace system or by obstructions in the form of vegetation would seem to be but partial palliatives at least so far as water action is concerned since when the water level is low the gradient at the bed may still be large while if the water level is high over soil of small permeability and the slope or obstruction is effective in keeping down the erosion coefficient it will hold up the run off and leave the land waterlogged What the water engineer requires is a system which will keep the shearing force on the bed small while not unduly impeding the run off above In the case of a river this desideratum may be secured by a series of check dams or shallow weirs placed at short intervals across its bed In this way the stream goes down a shallow staircase the main flow is unretarded but the motion near the bed is almost at a standstill Such a device is already in use to a certain extent on the Continent and the accompanying photograph shows how it is applied to the River Alp in Switzerland To combat sheet erosion on farm lands application of the same principle suggests the close sowing of dwarf herbage to impede the action of wind or rain within an inch of the soil while leaving free circulation above

CHECK WEIRS ON THE RIVER ALP SWITZERLAND

To measure the efficacy of such remedies it is necessary to take hourly or at least daily readings of the total silt load of rivers and farm drains and to correlate these with local rainfall Assuming the exponential relation between silt concentration and depth already noted it appears that measurement of concentration at two levels will suffice to determine the erosion coefficient this together with the average stream velocity, will determine the total rate of silt transport and hence the net total erosion above the observation station I have employed an apparatus for this purpose in the Tyne at Newcastle consisting of a pair of light beams and photo-electric cells placed at one third and two thirds of the depth below the surface, the mean flow being measured at the same time on a meter of the rotating vane type Hjulstrom has made measurements to the same end by actual weighing of silt samples taken out of the River Fyris at Uppsala It is really surprising what large silt loads can be carried annually by comparatively sluggish rivers. Thus Hjulstrom estimates that the Fyris—normally quite translucent—carries away more than 60,000 tons of material—soluble and insoluble—from its basin every year past the bridge at Uppsala. The figure for the more turbid and fast-running Tyne has not been precisely estimated; but it is considerably in excess of this

Research in Freshwater Biology in Great Britain

THE need for a biological station for research on problems connected with freshwaters was emphasized at the meeting of the British Association at Glasgow in 1928, and this led to the foundation of the Freshwater Biological Association of the British Empire in 1929 Two more years of active work on the part of the many men of science and others interested in the project elapsed before the laboratory was founded at Wray Castle on the shores of Windermere in 1931. At first there were but two members of staff, making the best of a few rooms without laboratory fittings, but from 1931 until the present year progress has been rapid, as is well shown by the recently issued sixth annual report*

The whole of Wray Castle is now occupied, there being on the ground-floor seven laboratories, fitted with adequate benches, sinks, electric light, power and gas, and upstairs a library, offices, and a number of living rooms capable of housing the unmarried members of the staff and up to a dozen scientific visitors There are now seven resident scientific investigators Dr E B Worthington (director), five assistant naturalists, and a bacteriologist, who cover all the major branches of the subject. These, together with secretarial and laboratory staff, should place Wray Castle among the foremost freshwater biological stations in the world, and make it capable of carrying out work of national importance

The interests most closely concerned with freshwater biology may be grouped into three categories—academic research, fisheries and water-supply—and each contributes materially to the finances of the Association. Accordingly, some limit has to be put to the scope of the work which is undertaken, those subjects being chosen which are likely to elucidate the factors which control the production of life, both qualitative and quantitative. The extent and variety of waters within easy reach of Wray Castle give ample scope for work on the many subjects involved

One promising line followed up during the past twelve months is connected with the bottom deposits of lakes With the co-operation of the Hydrographic Department of the Admiralty, a detailed bathymetric survey was made of Windermere by the new supersonic echo-sounding method The records revealed not only the depth of water but also the thickness of soft deposits overlying the glacial basin In addition, cores of the deposits have been obtained and appear to reveal a succession of cold and warm phases during the early history of the lake, so that a good opportunity exists for adding to knowledge of the post-glacial history of the district This research has more than historical significance because the use of the echo-sounding machine to demonstrate the thickness of soft deposits below a considerable depth of water has an immediate application to reservoirs, where the accumulation of mud may lead to greater production of algæ, and other troubles in filtration and purification of water for domestic purposes

Work in past years by Prof. W H. Pearsall, Mr R. Misra and others has demonstrated the great importance of the character of bottom muds in controlling the chemical (especially nitrogen) balance, and also the plant and animal associations Here an investigation at Wray Castle on the bacteriology of lakes, streams and bottom deposits, which is being financed by the Department of Scientific and Industrial Research, may be very significant Attention will be devoted by Dr. C. B. Taylor, who has been appointed to the new post, primarily to the part played by bacteria in the nitrogen and phosphorus cycles Closely linked with this is Dr. C H Mortimer's work on the chemical budget of a whole drainage basin. This has involved routine chemical analyses and the measurement of water-flows of rivers throughout the year, in order to estimate the quantity of different salts entering and leaving Windermere The effect of chemical factors on the growth of algæ is studied by Dr. M. Rosenberg by correlating the quality and quantity of algæ, as observed in natural conditions, with the chemical content of water at different depths and at different times of the year. In addition, many species of algæ have been taken into pure culture in the laboratory, where their reactions to altered conditions, in rate of multiplication and morphological change, can be studied under controlled conditions

---

* The Freshwater Biological Association of the British Empire Sixth Annual Report for the Year ending March 31st, 1938. Price to non-members, 1s.

This brings us to the work on animals, and here freshwater biology is still suffering under a disadvantage because the basic faunistic studies, such as were characteristic of the early work in marine biology, have never been properly undertaken The taxonomy of the aquatic stages of winged insects, for example, is still in a lamentable state, although work at Wray Castle on breeding ephemerids, caddis-flies and stone-flies is now helping materially in this direction It is in the hands of Mr T T Macan, who is working on the ecology of the Invertebrata, devoting special attention to corixid water-bugs Such studies are specially necessary in view of the importance of most of the groups as fish-food

Of the fish themselves, most attention has been given in the past few years to the salmon, the freshwater life of which up to the stage when smolts reach the sea is being studied by Mr K R Allen By detailed work in three widely separated parts of the British Isles, the Lake District, the extreme north of Scotland, and the south of England, he is obtaining comparative data of value in determining the factors which control their growth-rate and behaviour A new fish study is concerned with the so-called 'coarse fish', which contribute so much to the health and recreation of a large section of England's population This investigation has been financed by the fishing interests, and Mr P H T Hartley, recently appointed to undertake the scientific work, has a sure backing from the National Federation of Anglers

There is another aspect of the Association's work, connected with parts of the Empire other than Great Britain Already Wray Castle has served some purpose as a centre for information on freshwater fisheries in Africa, where the director has had extensive experience of research Local problems of fisheries or water-supply are bound to become more numerous as Colonial development proceeds, so that the Freshwater Biological Association may have opportunities of extending its usefulness in this direction

Viewing these activities as a whole, it may perhaps be fairly claimed that the laboratory at Wray Castle, though still young, is well on the way to becoming a worthy partner of its elder brother—one might almost say father—the Marine Biological Association's Laboratory at Plymouth

---

Analytical Methods in the Dating of Books and Documents

By Dr. Julius Grant

THE problem of establishing the date of origin of specimens of paper, for example, from books or documents, is one which arises frequently, but which is seldom solved without controversy In many such cases, suspected forgeries of valuable first editions of books are involved, whilst others are concerned with forgeries also, but possibly of greater criminological interest. Where written documents are in question, the ink expert has in the past usually been able to provide the strongest links in the chain of evidence, although with printed matter his contributions are necessarily restricted. However, since the date of the manufacture of the paper must always precede that of the application of ink (whether as handwriting or as print), the date arrived at as the result of an examination of the ink must always represent the paper as younger than it really is, and when the gap between the two dates is a big one, serious errors in dating may arise

In addition to that obtained from the ink, useful evidence has in the past also been drawn by the book expert from the nature of the type used, the format of the book, the binding, the illustrations and so on; these are all characteristics which demand an intimate knowledge of book production and its history In spite of this, there have been many instances where evidence of this kind, based as it must be largely on personal opinion, has proved inconclusive and even contradictory

The paper has, of course, also contributed its share of evidence, although not to the extent merited by the importance of the information it is capable of supplying This may have been due to inadequate co-operation between the experts on bibliographical and paper-making matters, and possibly to indifference to the interest and value of such studies on the part of the latter The importance of paper, particularly where the examination of first editions is concerned, depends to a great extent on the fact that, unlike printing type, the format of the book and so on, it is most difficult if not impossible to make a completely successful imitation of a given paper without employing the same materials and equipment as those used in the original Watermarks may be imitated, although these can now be detected with the aid of ultra-violet light (see J Grant[1]), and the character and appearance of a particular paper may be simulated, but as a rule a few comparatively simple analytical tests will reveal any essential points of difference.

Relatively new ground, therefore, was broken by J. Carter, and G. Pollard[2] when they used the fibre content of the paper as a means of dating it These workers were concerned principally with certain nineteenth century pamphlets, including works by Tennyson, Dickens, the Brownings and others, which were alleged to be genuine first editions Thus one particular case referred to a copy of Tennyson's "Morte D'Arthur" which was dated 1842 , when this was suspected, the fibre content of the paper was determined and was found to include esparto grass and wood pulp which had been prepared by a chemical process Since esparto was first processed in 1861 and wood some twenty years later, the forgery stood revealed without any doubt

It is apparent that the extension of this method of dating by reference to the introduction of a new raw material is full of possibilities, and since the work of Carter and Pollard this line of investigation has been pursued with highly successful results in many cases As explained below, however, there are many instances where the value of the method is only as a supplement to evidence obtained from the usual sources Two obvious conditions must in fact be satisfied in order that this type of test may be applied with any degree of reliability In the first place, the earliest date when the material in question was first used in paper-making must be known accurately , and in the second, a trustworthy method of establishing the presence of this material must be available Incidentally, as indicated below, one is not restricted to tests for the actual constituents of paper , new methods of manufacture serve the purpose equally well, so long, of course, as the two conditions specified above are fulfilled If enough characteristics of the above kinds can be assembled, it is conceivable that the date of origin of a paper may be 'sandwiched' between any two of them, and possibly be deduced to within a few years

There is no lack of suitable analytical methods for this work Unfortunately, there is less certainty regarding the years when some materials or processes were first used, and this places the principal restriction on the method Many innovations are not recorded in the literature, having been worked secretly in the first instance ; others are hidden in the obscurities of the early patent literature. In such cases, all that the method can do is to supply evidence that a paper which reacts positively to the test in question was made after the date of the earliest reliable record available. The importance of this proviso is greatest when papers made before the middle of the last century are under consideration, because the records of invention become progressively fewer as one goes back chronologically. In the future, on the other hand, this method of dating will become increasingly more valuable, because each year sees a fresh contribution to the technology of paper-making, and most of these can be detected and dated reliably.

Some examples of the application of these analytical methods will now be given. They fall into two main categories, namely, those involving the constituents of the paper, and those based on innovations in paper-making technique. As already pointed out, Carter and Pollard are the pioneers of the former method, although their work was restricted to tests for rag, wood and esparto fibres. This system may, however, be extended considerably, because several kinds of wood, as well as other fibres such as straw, are also used in paper-making

Up to the beginning of the last century, 'rag' fibres (that is, mainly linen or cotton) were the only materials of paper-making At about this time (1804) paper was first made by machine, as distinct from hand, and incidentally this is itself a reliable milestone, because a machine-made paper is easily recognized, and must be later than 1804 Owing to the rising standard of education, the demand for paper increased rapidly, and this led to an acute shortage of rags, the position being such that in 1854 a prize of £1,000 was offered by *The Times* for the discovery of a suitable substitute Straw was the first-comer in the field, and by 1860 mixtures of straw and rags were common , as they gradually declined in popularity (in Great Britain in any event) after the advent of esparto in 1861, such mixtures serve to date a paper as certainly later than 1855, and probably as between 1855 and 1870

Similarly, there was a transition period when mixtures of esparto and rag—a rare mixture nowadays—were quite common, and these serve to date a paper as certainly after 1861 and probably earlier than 1890 Wood was the next raw material, and of course in a relatively short time this became the most important of all fibres, at any rate so far as the cheaper grades of paper (for example, for books) were concerned ; full use of this is made by Carter and Pollard It should be pointed out, however, that within recent years the investigator has been enabled to distinguish between woods of different types and prepared by different processes, from a microscope examination of the disintegrated fibres of the paper. Incidentally, fluorescence microscopy in ultra-violet light (see J. Grant[1]) has proved of considerable assistance in this connexion It is thus possible to distinguish not only woods prepared by the mechanical process and by a chemical process but also woods prepared by different types of chemical processes (for example by the acid and alkali methods of digestion) and as the dates at which these processes were introduced are known accurately these analytical tests may prove of considerable aid in dating

Even to day new fibres continue to appear Bamboo is an example and it indicates that a paper is of Indian origin and probably later than 1930 Straw also can now be produced having a colour and degree of cleanliness which enable it to be used in fine papers and other recent additions to the paper makers fibres are bleached kraft alpha pulps and cotton linters these all have a certain amount of dating value so far as modern papers are concerned Incidentally the fibrous composition of a piece of paper may be ascertained by examination under the microscope of a few fibres scratched inconspicuously from the edge of the sheet this has obvious advantages where a valuable document is concerned

The fibres are not the only constituents of paper which have a dating value thus sizing materials loadings and colourings may all play a part Sizing provides an interesting example because there seems little doubt from the literature that rosin was first used for rendering paper non absorbent towards ink in about 1800 but that its use was confined to Germany until about 1835 Rosin in paper may be detected with relative ease and certainty and since the period around 1835 is one for which dating evidence is none too abundant this fills an important gap Loadings may be of interest partly because of their chemical nature and also by reason of the quantity present in the paper This is because when with the advent of machine made paper it became usual to sell paper by weight instead of by the sheet or ream many paper makers succumbed to the temptation to add to the former by the use of excessive quantities of loading The weakening effect on the paper was such that public opinion soon put a stop to this practice except for certain classes of paper (for example for the reproduction of illustrations) but there is a certain period (after 1820) when papers containing 30 per cent of loading were common Such papers are easily recognized because unless they have been stored under particularly favourable conditions the effects of ageing are strongly in evidence in many cases they fall to pieces at a touch (cf J Grant[4]) A recent addition to the loadings used in many papers is titanium dioxide and the white pigments associated with it these are easily detected and place the paper without any doubt as later than 1930

Coloured papers are seldom used for important documents although they can often supply very useful dating evidence Aniline dyestuffs for example were not used in paper to any great extent between the year of the discovery of the first of them (1856) and 1870 but after the latter date they became common The dating value in cases where the actual dye used can be identified is considerable because the patent records provide a trustworthy key to the history of the dyestuffs industry The mineral pigments used for colouring paper before the advent of synthetic dyestuffs also have a certain amount of dating value Ultramarine is the commonest of these and according to legend its use in paper originated from the mistake of a paper maker s wife who dropped her blue bag into her husband s pulp vat instead of into her own wash tub which stood adjacent to it in the home factory of those days Whatever the details of the discovery the date of its occurrence (about 1790) is known and as ultramarine is easily detected it may be used as an aid to the dating of blue papers of this period

Finally those improvements in paper making technique which have left their mark on the physical structure or character of the paper may have considerable dating value Watermarks provide one example although their importance as indicated above is limited The transition from hand made to machine made paper has also been mentioned while I have found that the use of the beater instead of the stamping mill to prepare the pulp is an important dating characteristic because it took place at a period (about 1670 on the Continent) for which little other dating evidence is available Unfortunately the identification of such paper which is carried out by examination of the fibres under the microscope is not always easy Calendered papers are however more easily recognized and date from 1830 and coated papers which are used for illustrations frequently serve to date the paper constituting the remainder of a book in which they are inset because it is known that they were first made in 1890

The examples given above might be supplemented considerably It is believed however that they suffice to indicate the possibilities of the application of analytical methods to the dating of paper As already pointed out the importance of the method should increase considerably as time goes on because of the increasing number of new methods and materials now being introduced into the industry and the fact that the dates of their introduction are known with accuracy

Obituary Notices

Prof. J. J. Abel, For. Mem. R.S.

NEWS of the death of John Jacob Abel on May 26 last was received with the deepest regret by pharmacologists all over the world as well as by a much wider circle of those who knew the man himself and could assess the value of his work and influence in advancing medical knowledge generally. He was one of the few surviving links with the beginnings of pharmacology as a separate discipline.

Abel was born at Cleveland, Ohio, on May 19, 1857, and entered the University of Michigan at nineteen years of age. He obtained the degree of Ph.B. there in 1883, after which he spent a year in graduate study at Johns Hopkins University. In 1884–88 he studied chemistry, physiology, pharmacology and medicine in various universities in Germany, and in 1888 took the degree of M.D. of the University of Strasburg. He spent a further two years in Vienna and Berne, and in 1891 returned to America as professor of materia medica in the University of Michigan. Two years later he became the first professor of pharmacology in Johns Hopkins University, a position which he held with so much distinction until his retirement in 1932.

The first Institute specially devoted to pharmacology was founded at Dorpat in 1847 by Rudolph Bucheim. Bucheim was succeeded at Dorpat by his assistant Oscar Schmiedeberg who, in 1873, was called to the University of Strasburg, and there established an Institute of Pharmacology, which soon attracted workers from all parts of the world. Abel was one of these, and he had thus, through Schmiedeberg, connexions with the beginning of pharmacological laboratories. When new positions in pharmacology were first created, most of those who were called to fill them had worked in Schmiedeberg's laboratory, and Abel from his work in this and other European universities came to have a personal knowledge of those men who afterwards became the pioneers of pharmacology throughout the world. Another of Schmiedeberg's pupils, A. R. Cushny, was selected by Abel to succeed him at the University of Michigan, and these two men exercised a guiding influence upon the development of pharmacology in the United States.

In 1909, Abel founded the *Journal of Pharmacology and Experimental Therapeutics*, which was the first pharmacological journal published in English, and in the editorship of which he was later joined by Cushny. The journal is now the organ of publication for both the American and British Pharmacological Societies. In all that concerned the early development of pharmacology in English-speaking countries—in the establishment of new laboratories, in the selection and training of young men to fill newly created positions and in providing a channel for the publication of their researches—Abel played a dominant part.

This influence, however opportune and important for the development of pharmacology, could not have become so great had it not been supplemented and vitalized by the brilliance of Abel's personal achievements and by the example of his patient and persistent devotion to research. One of his earliest investigations was concerned with the occurrence of aliphatic sulphur compounds in the animal body. This experience helped him later in the successful crystallization of insulin, for he had found that fractions of insulin preparations contained labile sulphur in proportion to their hypoglycæmic power. He was one of the earliest workers on hormones, and succeeded in obtaining an active principle of the suprarenal gland in the form of a monobenzoyl derivative which he called epinephrine. Later Takamine obtained the free base, adrenaline. The determination of the chemical constitution of adrenaline and the discovery that it was a relatively simple body gave an impetus to that study of the constitution of other hormones which has developed so rapidly in recent years. Abel himself later found adrenaline in the secretion of the skin glands of the toad, *Bufo agua*.

In another direction Abel did pioneer work, in devising a method, 'vividiffusion', whereby blood from a living animal could be diverted through a dialysing apparatus and then returned to the body. A study of the dialysates showed the constituents that occur free in the blood.

Abel also studied the active principles of the poisonous mushroom, *Amanita Phalloides*, and found two active principles, a hæmolysin and a non-hæmolytic toxin, the latter being responsible for the toxic effects of the fungus when ingested. Abel and Rowntree investigated various phthalein derivatives with the primary object of obtaining a purgative suitable for hypodermic use. They found that phenolphthalein was excreted solely by the kidney, and this led to its use later as a test for the functional activity of the kidney. Halogen substitution products of phenolphthalein were found to be excreted in the bile only, and this led to the development of tests for liver function by such compounds.

Abel worked also on the action of convulsant dyes, on the physiology of the lymph hearts of the frog, and did some of the early work in the newer domain of chemotherapy in his investigation of the action of antimony compounds in experimental trypanosomiasis. His work covered a wide field, as did that of most of his contemporaries in pharmacology, and was always characterized by imagination as well as by the skill and tenacity with which he pursued a problem.

After his retirement in 1932, Abel still had a room in Johns Hopkins University and up to the end was actively prosecuting researches on tetanus toxin. I still retain a vivid memory of listening to Abel, three years ago, when he outlined the purport of this investigation with all his wonted enthusiasm and modesty.

Abel was the recipient of many academic honours and became honorary or foreign member of many learned societies in many countries Perhaps none would have given him greater pleasure and satisfaction than his election as foreign member of the Royal Society, which took place only a few days before his death

During the time in which pharmacology has been emerging as a separate science with its own laboratories and followers, Abel has been an outstanding personality to whom that science must for ever remain in debt His tall spare figure and genial presence will be sadly missed not only in his own country but also wherever men forgather who are interested in the progress of medical research J A GUNN

Sir Colin Mackenzie

WE regret to announce the death of Sir Colin Mackenzie, formerly director of the Australian Institute of Anatomy, at the age of sixty one years

Though Sir Colin gained great distinction as an orthopædic surgeon yet he devoted himself to anatomy with an enthusiasm that might be expected to flow only from great genius He was lecturer and examiner in anatomy in the University of Melbourne He was a member of the Anatomical Society, served eagerly the Zoological Society of his city, established and furnished a whole museum with dissections of marsupials, strove to secure the preservation of the Australian fauna, and wrote their comparative anatomy in four volumes His faith in anatomy induced the Commonwealth Government to erect in its Federal capital an anatomical institute under his direction

Sir Colin's book, 'The Action of Muscles', contains an epitome of his anatomical observations and ideas In about fifty pages, under the title of principles, he states what he has come to believe about muscles The reader is constantly referred to what happens in the wombat, frequently assured that the action of muscles can only be understood by an appeal to their evolutionary history, and is admonished to consider the behaviour of the primates and the assumption of the erect posture The principles which he enunciates owe nothing to these allusions to the primates or to the illustrations of marsupial anatomy The dissections of the wombat seem quite irrelevant to his principles of muscle action which have to do with the treatment of paralysis

More than thirty years ago, when the treatment of fractures and muscular palsies was very bad, Mackenzie was preaching and practising his principles He pointed out the error of describing a muscle as paralysed because it was unable to perform its maximum amount of work More careful inquiry might discover that such a muscle still had some power The muscles of the shoulder might not be able to lift the limb against gravity, yet perhaps could swing the arm from the side when the body was horizontal and gravity thus excluded Inflamed nerve cells like any other inflamed tissue must be put at rest A motor nerve cell could only be rested through its muscle A muscle is placed in a state of physiological rest when its antagonists are kept over stretched Thus by rest, and then utilizing the residual power left in an affected muscle, by patience and persistence he accomplished much Muscle and tendon transplants were advised only when re education seemed hopeful He cut through much that was unimportant in the teaching of muscle action by his blunt insistence that a muscle had always one prime action to perform and only co operated fully in other actions after its prime action had been fulfilled He insisted upon muscle re education and saw that this was only hopeful when the alteration of the attachments demanded the least change in function and when there was greatest cerebral control Thus the gain in usefulness was in general far greater in the arm than in the leg

His work in mitigating the terrible consequences of infantile palsy led to far greater interest in these matters His experience was made available in the orthopædic hospitals of Great Britain during and after the Great War In his own city more people skilful in these matters are available than perhaps anywhere else He deserves an honourable place amongst The Menders of the Maimed

Miss D M Liddell

WE regret to record the death, which took place on May 25 at the Old Rectory, Stratfield Turgis, Basingstoke, of Miss Dorothy Mary Liddell, well known as an experienced and fortunate excavator on archæological sites

Much of Miss Liddell s early experience and training in archæological work was gained by her participation in the excavation of the famous Windmill Hill site of neolithic culture, explored by Mr Alexander Keiller The effect of this training, combined with a natural flair for archæological work, were used to full advantage in her discovery and patient exploration of the Roman house at Lodge Farm, North Warnborough, and also in the discovery and examination under the auspices of the Hampshire Field Club of the extensive pit dwellings at Chosely Farm, Odiham Previously she had spent some seasons at work on Chilworth Ring, on Meon Hill Her most lasting contribution to archæological analysis, however, is probably the patient and detailed study she made of stamped impressions on neolithic pottery The results of prolonged examination of innumerable specimens of potsherds and of a prolonged series of experiments and photographic work were embodied in an article in *Antiquity* in 1929, "New Light on an Old Problem", in which the central idea of the use of bird bones as an instrument of ornamentation had been suggested to her by the discovery of a large quantity of "West Kennet" pottery associated with a small bird bone

---

WE regret to announce the following deaths

Prof E W Brown, F R S, emeritus professor of mathematics in Yale University, an authority on lunar theory, aged seventy one years

Mr G Nevill Huntly, consulting chemist, on August 2, aged seventy one years

News and Views

L'Abbé Breuil

M. l'Abbé Breuil, professor in the Institut de Paléontologie Humaine and of prehistory in the Collège de France, has been elected a member of the Académie des Inscriptions et Belles Lettres. This signal honour is conferred in recognition of his work in prehistory and more especially of his studies of the art of the palæolithic age. The Abbé has now been recognized for nearly a generation as the foremost authority on prehistoric archæology not only in France, but also in the whole world; and his opinion on any disputed point is universally regarded as a court of final appeal. His election to the Academy is a matter of peculiar gratification to his colleagues in France, as it is the first occasion on which the study of early man and his culture has been honoured officially in this manner; for although de Quatrefages was a member of the Académie des Sciences and Hamy of the Académie des Inscriptions, while Cartailhac was a corresponding member at Toulouse of the latter body, they received these honours, as the editor of *L'Anthropologie* points out in the current issue (48, 1938, p. 391), not in virtue of their eminence in anthropological studies, but on the ground of other qualifications—de Quatrefages as zoologist, and Hamy for his work on the history of geography and geographical exploration.

Dr. Leo Jolowicz

On August 12, Dr. Leo Jolowicz will celebrate his seventieth birthday. For many years he has occupied an outstanding position in the German scientific book and publishing business, and has done very much to foster and promote the development and diffusion of the results of scientific research. About fifty years ago, he took over the book business of Gustav Fock in Leipzig, which under his leadership became the largest and best-known 'Antiquariat' of scientific books. Dr. Jolowicz founded the famous publishing house, the Akademische Verlagsgesellschaft. This firm publishes a large number of well-known scientific journals, including, for example, the *Zeitschrift für physikalische Chemie*, and many important standard works and reviews, among which may be mentioned the "Handbuch der Experimentalphysik", "Handbuch der Radiologie", "Rabenhorst Kryptogamen-Flora", "Bronns Klassen und Ordnungen des Tierreiches", "Ergebnisse der Enzymforschung", "Ergebnisse der Vitamin- und Hormonforschung", etc. Among the world's famous publishers who through their deep interest in, and knowledge of, science and learning and their enterprise and imagination do so much to promote the advance of civilization, Dr. Jolowicz occupies a prominent and honoured position.

George James Symons, F.R.S. (1838-1901)

On August 6, occurs the centenary of the birth of the distinguished meteorologist George James Symons, in whose honour the Symons Medal of the Royal Meteorological Society was founded. Born in Queen's Row, Pimlico, he was educated at St. Peter's School, Eaton Square, London, and at Thornton Rectory, Leicestershire, and passed through the Royal School of Mines. Having joined the British Meteorological Society in 1856, the following year he undertook the duties of meteorological reporter to the Registrar-General, and these he continued to discharge until his death. For three years, 1860–63, he also served under Rear-Admiral Robert FitzRoy in the Meteorological Department of the Board of Trade, which had been inaugurated in 1857. His services to meteorological science were many and varied. In 1860 he published the first volume of his "British Rainfall", which gave rise to the British Rainfall Organization, the work of which was transferred to the Meteorological Office in 1919, and in 1866 he founded *Symon's Meteorological Magazine*, which in 1920, with the *Meteorological Office Circular*, was incorporated with the *Meteorological Magazine*. For two periods he served as honorary secretary to the Royal Meteorological Society, and in 1880 and 1900 was the president. So early as 1876 he received a Telford premium from the Institution of Civil Engineers for a paper on floods and water economy, and in 1897 he was awarded the Albert Medal of the Royal Society of Arts for the service he had rendered engineers engaged on water supply problems. His death took place on March 10, 1900, and he was buried in Kensal Green Cemetery. The following year a fund of more than £700 was subscribed for founding the Medal bearing his name.

Sir James Barrett's Reminiscences

Sir James Barrett, chancellor of the University of Melbourne, has contributed to *The Herald* (Melbourne) during April and May of this year a series of reminiscences which deal with the history of old Melbourne and its University and Hospital, early days in London and on the Continent, recollections of the Great War, and education and university extension in Great Britain and the United States. Born and spending his boyhood in old Melbourne, when there were toll gates on the St. Kilda Road, Sir James entered the University there when he was fifteen years old, and graduated in the medical faculty in 1881. He recalls the kindly assistance given to students by Prof. Halford, who taught anatomy, physiology and pathology, at a time when the University had only two hundred students with five professors to teach them, and describes medical practice in Melbourne Hospital in those pre antiseptic days He proceeded to London in 1883, obtained the fellowship of the Royal College of Surgeons, London, became demonstrator of physiology in King's College, London, under Gerald Yeo, and commenced his career as an ophthalmic surgeon as assistant at Moorfields Eye Hospital Interesting recollections are given of Bowman, McCarthy and Michael Foster Gaskell and Langley, and Jonathan Hutchinson and Whittaker Hulke, all well known figures in the medical world of the time, he also visited the Continent, and met Koch in Berlin Then come recollections of the Great War, and the organization of the medical service in Egypt The organization of "bush nursing centres" in Australia is recounted, a scheme initiated in 1908 by the Countess of Dudley, and finally, Sir James has a good deal to say upon education and university extension, and recalls some of his meetings with British statesmen

The British Medical Association: Plymouth Meeting

DR COLIN LINDSAY presided at the one hundred and sixth annual meeting of the British Medical Association, held at Plymouth on July 19 and following days "The Profession and the Public" was the title of the address of Dr Lindsay, who pointed out that his remarks were based upon an experience of forty years as general practitioner and consulting physician He emphasized the need for continued education both for the public and for the practitioner, and the necessity that exists for a specialist service to supplement the service of the family doctor, for medicine has grown so enormously that it is quite impossible for any one person to be proficient in every branch He reminded the public of the unity and equality of the three main branches of the profession—the general practitioners, the consultants and the members of the public health service—which are essentially complementary, each requiring for its proper performance attainments of the highest order He desires to see more attention paid to the treatment of the so called 'minor ailments', for it has been estimated that forty per cent of all sickness is due to the patient's own action The principle of free choice of doctor' under National Health Insurance was stressed, and the Association's proposals for a general medical service for the nation were outlined, by which members of families within an income limit of £250 a year would be included Other topics dealt with were the fees to be paid for consultative work, the education of the public in the use of the doctor, and the countering of credulity on the part of the public

Lister Institute of Preventive Medicine

THE report of the Governing Body of the Lister Institute of Preventive Medicine, presented at the annual general meeting on June 2, gives an account of the researches carried out at the Institute during the past year. Several studies on viruses, vaccinia and others, are detailed, with an investigation on the problem of rheumatic diseases, in which virus like bodies occur. Dr Felix and others have continued their work on the antigenic constitution, virulence and immunizing properties of bacteria and Protozoa, and the chemistry of bacterial antigens has also been investigated The Svedberg velocity ultracentrifuge, installed some time ago, has given satisfactory service, and several proteins have been the subject of study with this instrument Many studies on vitamins, their chemistry and action have been prosecuted by Dr Harriette Chick and her co workers The Institute is the home of the National Collection of Type Cultures, and more than 6,000 cultures have been distributed to workers at home and abroad Sir John Ledingham, the director, his staff and attached workers may be congratulated on their fine output of work

Medical Classics

Two important medical classics which were recently published in the *Bulletin of the Institute of the History of Medicine* have just been reprinted in book form and thereby made accessible to a wide circle of readers The first of these, entitled 'On Thought in Medicine', is the address delivered by Hermann von Helmholtz on August 2, 1877, on the anniversary of the foundation of the Institute for the Education of Army Surgeons In this address, Helmholtz attacks the old educational system which he regards as pursuing a false idea of science, in which there is a one sided and erroneous reverence for the deductive method Medical education during the early part of the nineteenth century in Germany was based mainly on the study of books There were no physiological or physical laboratories, and microscopical demonstrations were infrequent in lectures It fell to Johannes Muller and his pupils, of whom Helmholtz was one, to stimulate the study of microscopical and pathological anatomy, experimental pathology and therapeutics and to substitute experimental research for untried and unconfirmed hypotheses

THE second volume contains a translation of Ivan Sandström's work entitled 'On a New Gland in Man and Several Animals (Glandulæ Parathyroideæ)", which was published in vol 15 of the Swedish journal *Upsala Lakareforenings Förhandlingar* for 1879–80, and represents the first detailed description of the parathyroid glands, based on the naked eye and microscopical examination of these glands in the dog, cat, rabbit, ox and about fifty human subjects It is noteworthy that whereas the translation of Helmholtz's address was published so long ago as 1893, the English version of Sandström's monograph now appears for the first time, and has been carried out by Dr Carl Seipel, who has also translated an account of Sandström's life and work by Prof A J Hamman of Stockholm

Jubilee of the Gypsy Lore Society

THIS year the Gypsy Lore Society celebrates the fiftieth year of its existence The occasion was marked by a jubilee dinner on June 11, over which Lady Arthur Grosvenor (president, 1913–14) presided in the unavoidable absence of the president, Mr. Augustus John, and at which fifty five members and guests were present. The Gypsy Lore Society was founded in 1888 by Charles Godfrey Leland ('Hans Breitmann') and David MacRitchie of Edinburgh. Leland's enthusiasm for gypsy studies, characteristically overpowering, dated from 1870, when he settled in England for a period of years. Although he wrote several books on the gypsies between 1873 and 1882, it was not until 1888, three years after his return to England, that his desire to promote a wider interest in the investigation of the gypsy problem took practical shape in the foundation of a society devoted to that object; and indeed its formation was owing largely to his association with the organizing ability and scholarly habit of mind of MacRitchie, to whom also was due, with John Sampson and R. A. S. Macfie, the resuscitation of the Society in 1907, when it had been dormant for a period of years through lack of funds. Among the eleven original members, who formed the nucleus of the Society, were H. T. Crofton, Elizabeth Robbins Pennell, Leland's niece, famous as an interpreter of Ibsen's heroines on the stage, the Archduke Joseph of Austria, a fluent Romani linguist, Sir Richard Burton, the famous, if difficult, orientalist and traveller, Paul Bataillard, F. H. Groome, most eminent of the early students of gypsy folk lore, and Walter Herries Pollock; while one of the earliest adherents in the United States was Mary Alicia Owen, later known as an authority on the folk lore of the American Indian, whose early studies of the traditional tales and beliefs of the negroes of Missouri, if modelled on the 'Uncle Remus' of Georgia of Joel Chandler Harris, were directly inspired by Leland's encouragement.

In an introductory article which opens a special jubilee number of the *Journal of the Gypsy Lore Society*, the editor, Archdeacon F. G. Ackerley, enumerates some of the more noteworthy contributions to the investigation of the gypsy problem which have appeared in its pages and elsewhere since the foundation of the Society. Among contributors to the *Journal*, the late Dr. John Sampson naturally takes a high place, not only on account of his linguistic studies, but also for his collection of Welsh Romani folk tales; but it will be generally agreed that the term 'epoch-marking' here applied to Prof. R. A. S. Macalister's collection of material bearing on the language of the Nawar of Palestine is appropriate in more than a conventional and complimentary sense. It gave a new orientation to the study of the gypsy problem. Outside its own publications, the influence of the Society is to be seen in Dr. John Sampson's "Dialect of the Gypsies of Wales" (1926), which has been termed "the best of all Gypsy linguistic studies in any language" and Prof. E. Pittard's "Les Tsiganes ou Bohémiens" (1932) in which "is presented once and for all the physical anthropology of the race". Two great services the Society has performed for gypsy studies: it has abolished the pseudo-romantic rubbish which formerly passed for gypsy lore, and it has exploded the popular association of gypsies with Egypt by laying down the true lines for the investigation of the problem of their origin. It is difficult to say which has been the greater service to learning.

Archæological Collections in Spain

Notwithstanding reports of damage sustained by archæological collections in the museums of Madrid, it is now announced that an official verification by the Ministry of Public Instruction and the Municipality of Madrid has established the fact that the collections of both the Archæological Museum and the Anthropological Museum of Madrid are intact. Prof. Bosch Gimpera, to whom the editors of *L'Anthropologie* (48, 3–4; 1938) are indebted for the information, goes on to add that the other museums of the area under the Republican Government have been preserved from damage, while the official departments responsible for antiquities are taking every necessary precaution for their safety. As regards the museum at Valencia and the Catalan museums, Prof. Bosch Gimpera, as head of the antiquities service, is able to give his own personal assurance of their safety to his archæological colleagues outside Spain.

Italian Anthropological Expedition to Erythraea

On his return at the close of last year from an expedition to the Tana basin of Ethiopia, Prof. L. Cipriani, director of the Anthropological Laboratory of the University of Florence, was forthwith placed in charge of an anthropological mission to northern Erythraea for the purpose of studying the little known peoples north of Cheren. This mission was under the joint auspices of the Royal Academy of Italy and the Bureau of Colonial Studies of Florence. The expedition lasted from December 1937 until March 1938. According to a preliminary note of the results (*L'Anthropologie*, 48, 3–4; 1938), anthropometric measurements were made of 450 subjects, of whom there were 70 Bogo, 94 Mària, 26 Habab, and 159 representatives of groups adjacent to the last-named. For purposes of comparison, measurements were also made of 29 Abyssinians, as well as 30 Baria women and 20 Rasciàida. The blood groups were tested in 110 subjects. A further result of the expedition was the discovery of a large number of rock paintings in the granite caves of Carora near the Anglo-Egyptian frontier, as well as of stone implements of palæolithic type, the first to be recorded in Erythraea. Finally the expedition brought back to Italy 68 masks taken from the living, and more than two thousand photographs of ethnographical and anthropological subjects.

Stone Age Village in Yorkshire

Now that archæological research aims at the reconstruction of a cultural phase as a whole, rather than at bringing to light by excavation individual antiquities of exceptional interest or artistic merit, the announcement of the discovery of a remote but complete village of the stone age at Rinyo on the Island of Rousay, Orkney (*The Times*, July 29) has an importance which transcends the intrinsic interest of any individual object likely to be obtained there

General Chemistry

By EUGENE P. SCHOCH
Professor of Chemistry, University of Texas
and WILLIAM A. FELSING
Professor of Chemistry, University of Texas

524 pages, 8 × 5½, 74 illustrations, 18/- net

(International Chemical Series)

THIS new book shows the beginning student how a chemist performs the various operations or solves the various chemical problems which come to his attention. The operations and problems are arranged in a progressive manner, and the subject matter is therefore divided according to the fundamentally different types of chemical reactions, beginning with very simple types. Laboratory directions are interspersed with the main portions of the text.

Contents

- Preface
- Special Introductory Laboratory Exercises
- Fundamental Facts
- Energy Changes in Chemical Reactions Illustrated by Reactions Involving Oxygen
- The Gas Laws, The Kinetic Molecular Structure of Gases and of Condensed Forms (Liquids and Solids)
- Simple Reactions between Metals and Acids, the Preparation and Properties of Hydrogen, Some Properties of Solutions
- Reversible Chemical Reactions A Third Illustration of Equilibrium
- Acids, Bases and Salts
- The Periodic Classification of the Elements and the Structure of Atoms
- The Ionization of Acids, Bases, and Salts, Metathetical Reactions
- A Study of Some of the Properties of the Elementary and Compound Forms of Carbon and Silica
- The Properties of Sulphur and of Some Sulphur Compounds
- Properties of Nitrogen, Phosphorus, and the Halogens and of Some of Their Compounds
- The Colloidal State
- The Relative Weights of Molecules
- The Actions and Uses of General Reagents for Solutions of Salts
- A System of Qualitative Analysis for the Common Metal and Acid Radicals
- Electrolysis, The Chemical Changes at the Poles of Electrolytic Cells
- Battery Action
- Electronic Change or Oxidation reduction Reactions
- The Preparation and Properties of a Few Common Metallic Elements
- The Fundamental Principles of Organic Chemistry and the Chief Types of Organic Compounds
- Animal and Vegetable Fats and Oils, Carbohydrates, and Nitrogenous Food Constituents
- Appendix
- Index

Problems in Organic Chemistry

By ERNEST HAMLIN HUNTRESS
Associate Professor of Organic Chemistry, Massachusetts Institute of Technology

270 pages, 8 × 5½, 12/6 net

(International Chemical Series)

INTENDED to supplement the use of a regular textbook in organic chemistry, this new book offers a collection of problems, questions, discussion topics, and review exercises. The book is divided into three main sections: the first is devoted to the mono-functional compounds of the aliphatic series, the second to corresponding compounds of the aromatic series, and the third to poly-functional compounds and compounds with more than a single type of function drawn from either or both series.
Each of these three main divisions is subdivided into parts, each of which deals mainly with some definite class of compounds. Certain parts are still further subdivided into sections with closely similar classes. Each part is so constructed that after suitable drill in the simpler aspects of the behaviour of its particular class of compounds, attention is drawn to the co-ordination and cumulation of the class with the classes which have preceded it. The author emphasizes this principle of "co-ordinative cumulation" as a means of development of power in the subject.

CARNEGIE INSTITUTION OF
WASHINGTON

Is a research organization working in many fields. Its monographic publications are placed in the principal libraries of the world. Copies can be purchased at nominal cost.

These publications comprise studies in the following fields:

ARCHÆOLOGY
ANTHROPOLOGY
ASTRONOMY
BIOLOGY
BOTANY
CHEMISTRY
ECOLOGY
ECONOMICS
EMBRYOLOGY
GENETICS
GEOLOGY
HISTORY
LITERATURE
MATHEMATICS
NUTRITION
PALÆONTOLOGY
PALÆOGRAPHY
PHILOLOGY
PHYSICS
TERRESTRIAL
MAGNETISM
ZOOLOGY

MACMILLAN'S NEW BOOKS

The Native Tribes of Central Australia

By SIR BALDWIN SPENCER,
and F. J. GILLEN

With a Preface by **Sir James George Frazer, O.M., F.R.S.**

Sir James Frazer writes. "It is a very important volume, for it contains a detailed account of the Arunta Tribe of which both authors were fully initiated members, it also comprises the description of other important tribes, which description was not afterwards reprinted by the writers. From the nature of the case, in the present decadence of the native tribes, the book can never be superseded It is an anthropological classic, a possession for ever" **New Edition.** 133 *Illustrations and 2 Maps* 25*s. net.*

Studies in the Philosophy of Religion

By ARCHIBALD ALLAN BOWMAN, Litt.D.
Sometime Professor of Moral Philosophy in the University of Glasgow

Edited, with a Memorial Introduction, by **Norman Kemp Smith, D.Litt., LL.D., F.B.A.,** Professor of Logic and Metaphysics in the University of Edinburgh

This work by the late Professor Bowman was already completed in first draft in 1925; but he kept it by him, and continued to revise it up to the time of his death It should prove of the first importance to all students of the philosophy of religion, whether their interest is primarily metaphysical or primarily theological. **2 Vols.** 30*s net*

Coordinate Solid Geometry

Being Chapters I—IX of "An Elementary Treatise on Coordinate Geometry of Three Dimensions"

By ROBERT J. T. BELL, M.A., D.Sc., LL.D.
Professor of Mathematics in the University of Otago, Dunedin, N.Z

There is a number of students whose interest in pure mathematics does not extend beyond the requirements of pass degree examinations in mathematics. The first nine chapters of Professor Bell's well-known treatise, completing the work on the central surfaces, is sufficient for these. He has accordingly arranged to issue this portion of his book, with some additions and alterations, as a separate volume. 7*s.* 6*d.*

Metal-Mining Enterprise

Warington Smyth Memorial Lecture, 1938

By PROF. S. J. TRUSCOTT, D.Sc., A.R.S.M., M.Inst.M.M.

"Sir Warington Smyth was the first professor of mining at the Royal School of Mines, and his forty years of service coincide with one of the most momentous changes in the history of the world, namely, the growth of industry on a metallic foundation. Prof. S. J. Truscott showed, in his Warington Smyth Memorial Lecture delivered on May 5 (and here issued in book form) how to-day everything civilized man enjoys depends on metals."—NATURE. 1*s. net.*

In the present instance, there is added its bearing on the site of Skara Brae, the similar village discovered and excavated some ten years ago, of which the significance for our knowledge of stone age culture and more of life was such that Prof V. Gordon Childe at the time described it as a veritable Knossos of the north The new site defines more nearly the dating of the culture, left somewhat indeterminate, at Skara Brae The discovery of a portion of a beaker, in association with objects of the Skara Brae type, fixes the period of occupation at somewhere about the transition from stone to bronze in Great Britain, that is at about 1500 B C. Further the Rinyo village, being apparently complete, should supply details which at Skara Brae had been swept away by the encroachments of the sea on the sand dunes The Rinyo settlement has been excavated by Mr Walter W. Grant, with whom has been associated Prof Gordon Childe Below the floor in which the beaker fragment was discovered, traces of earlier occupation have been found These are in the form of commodious stone houses, provided with recesses for beds, built dressers and even a system of drainage In addition to open hearths, some of the houses have clay ovens, a novel feature It is anticipated that eventually excavation will give a complete picture of a whole stone age settlement, unique in Britain, and indeed in western Europe, and at the same time throw a new light on the social organization and economy of a neolithic community

Rhodesian National Museum

IN reference to the announcement of the proposed National Museum for Southern Rhodesia in the neighbourhood of the Zimbabwe ruins (see NATURE, July 9, p 65), Mr F M Collins writes to suggest the possibility of a confusion between the Victoria Falls and Fort Victoria, the township one hundred and eighty miles east of Bulawayo, near which the ruins are situated, while their distance from the Falls is by air approximately four hundred miles 'Proximity', however, the term in the comment in these columns to which Mr Collins takes exception, is, as he admits, relative, and as the general sense indicated was used in comparison with, for example, the distance from Cape Town, which would affect students and tourists, rather than in relation to absolute mileage

Science and the Way to Peace

AN "Appeal to the Scientists of the World" has reached us from India The author, Dr Bhagavan Das of Benares, a member of the Legislative Assembly of India, refers to the imminent peril of another world war, far surpassing the last in horror and destructiveness, and the frightful strain meanwhile imposed on mankind by preparation for defence He seeks to show that a heavy responsibility for this state of affairs rests on the learned world as a whole, partly because modern warfare owes its peculiarly devastating character to scientific research and the collaboration of men of science with the organizers of war and partly because the ideas that motivate wars are products of the speculations of philosophers and the vulgarization and misapplication of theories invented by men of science, notably that of the ascent of man through the struggle for existence and survival of the fittest. He quotes from the records of ancient Aryan wisdom: "Science (Vidya) came to the man of wisdom, the man of knowledge and purity, and said to him . guard me as a sacred trust, give me not to the wicked and sinful, but only to the pure of heart and large of mind, so only will I be strong to nourish mankind, otherwise I will only destroy thee and thy pupils and thy people" So in our own day Alexis Carrel in "Man the Unknown" writes. "The environment which science and technology have succeeded in developing for man does not suit him because it has been constructed at random without regard for his true self." Therefore, the appeal says, it is "up to" the learned world to get together and do something about it. Peradventure where politicians have failed men of science may find a way of approach to disarmament, military and economic

The Ontario Research Foundation

THE report of the Ontario Research Foundation for 1937 (Sessional Paper, No 52 Pp 35 Toronto King's Printer) refers to an increase in the amount of research work carried out in contact and in co-operation with industrial companies, the revenue received for services rendered to industry itself having increased by thirty per cent. The Textiles Department has during the year developed a launderometer for determining the fastness of dyed goods to washing, a fadeometer for determining the fastness of coloured fabrics to light, a crock meter for determining fastness of dyes to rubbing, and an autographic tensile strength and elongation tester for determining the strength, extensibility and yarn slippage of materials. The Engineering and Metallurgy Department continued its investigation on summer comfort standards for the Toronto district and also its study of the resistance to abrasion of iron and steel balls under the conditions existing in the grinding mills of mines In the Department of Chemistry, the development of a laboratory for the study of problems relating to paper, printing and adhesives has been completed Work on the transfer of pigments from aqueous pastes to an oily medium by methods which are commercially feasible has reached its final stages and in addition to the mechanical problem an emulsifying agent is required which is not detrimental to the final product The equipment and organization of a laboratory for the study of plastics has been commenced, and a new laboratory has also been inaugurated to study problems associated with the manufacture of waxed paper and similar products. The Department of Biochemistry has continued its investigations on a combined system of tannage for sole and belting leather and on problems connected with the Matzka process for the preparation of fruit juices which are stable for prolonged periods and retain their original flavour and content of vitamins. Investigations carried out by the Department of Agriculture have related to mineral deficiencies of land types and the relation between soil, climate and cultivation of the principal crops in Ontario, while the Department of Pathology and Bacteriology has continued its studies of bovine mastitis and the parasites of sheep

The Carnegie Institution of Washington

THE Yearbook of the Carnegie Institution of Washington, July 1, 1936–June 30, 1937, contains the reports of the Executive Committee and of the president for the year ended October 31, 1937, together with reports on investigations received up to December 10 and a bibliography of publications issued during the year by the Institution or of the Institution's staff through all channels (Washington Carnegie Institution of Washington) The president's report again refers to the relations between science and social problems and to the importance in society not merely to appreciate the difficulties in interpretation of the influence of science but also to be aware of the interdependence among social elements in the same way that we are aware of the interrelations among elements involved in the unity of Nature The Geophysical Laboratory has continued researches to determine with all possible precision the underlying causes of geological and geophysical phenomena A major advance in the terrestrial magnetic research is reported by Dr J A Fleming, in the proof of the association of a special type of magnetic disturbance and sharp fade outs of high frequency radio wave reflections with bright eruptions in the solar chromosphere With this advance, the Mount Wilson Observatory was also associated, and the Observatory also expanded greatly the scope of solar investigations with the rapid increase in solar activity The Division of Plant Biology has continued to study the ecology of the Great Plains and its bearing on the agricultural and human population of that area The Division of Animal Biology has made several observations fundamental to the cancer problem, and the value of diverse approaches by different groups of workers is well illustrated in this work as in reports from the Divisions of Embryology, the Nutrition Laboratory and the Department of Genetics in the field of endocrinology

Technical Colleges of South Africa

THE Carnegie Corporation of New York has lately issued a critical study by Dr F H Spencer of the technical colleges of South Africa Dr Spencer has had experience of technical education in Great Britain, and this has enabled him to make some interesting comparisons The technical colleges provide (*a*) full time pre apprenticeship courses for pupils aged 14–17 or 18, (*b*) part time courses for apprentices and others already at work. The place accorded in the full time courses to general cultural work is, by British standards, inadequate, geography being dropped after the first year, while history, even from the economic point of view, does not enter the picture The part time courses, which are everywhere the largest part of the technical college work, are dominated by the Apprenticeship Law This enactment has conferred on South Africa some of the benefits which in Great Britain should have resulted from the clauses of the Fisher Act providing for daytime continuation education from 14 to 18 In South Africa, despite a certain amount of recalcitrance, the Apprentice Law is an undoubted success Apprentices attend ordinarily about eight hours a week of which half is taken from day time working hours The great merit of the system is that the compulsory attendance is almost universally followed up to an advanced stage by a not unsatisfactory proportion of the apprentices This advanced stage at least for the constructional trades, is comparable with university work, and those who pass through it to the national certificate stage will furnish the 'non commissioned' staff of industry who are as essential to success as the management

The Belgian Grid

IN *Electrical Industries* of July, W Fennell gives a review of the salient engineering features of the Belgian Grid, which began by the co operation in 1919 of isolated supply companies These companies, mostly in the southern and eastern provinces (Liège, etc), happened to be in close contact with heavy industries They realized the existence of by product power going to waste' at the large industrial works and saw that in some cases it would be economical to use this power rather than to build large power stations or extend small ones A power production combine was formed to further the interests of manufacturers who had blast furnace and coke oven gas and process steam available greatly in excess of their own power requirements In addition, they had engines used as stand by plant, much of which would not be necessary if the various works' plants were interconnected The electricity supply companies also had means of utilizing the waste power This combine has spread so that it includes practically the whole country under a grouping system All the undertakings and associated works are linked up into two networks, north and south, which are themselves interconnected The production of power, while remaining under local control, is directed by a national co ordinating company The tariff applied to plant owners is based on the principle that the amounts they pay or receive are equal to the reduction or increase of expenditure entailed in their installations by running in parallel, compared with independent working The success that Belgium has attained as a competitor in the steel and chemical industries indicates that this co operative experiment, now twenty years old, has been a substantial contributory cause

Conservation of Natural Resources

UNDER this title, the American Association for the Advancement of Science has issued a selected list of literature dealing with various aspects of the subject Almost too late, rather than too soon, the United States is becoming conscious of the significance of the vast subject of conservation The very word is itself indicative of a more sober outlook The falsely alluring concept of limitlessness which in the last century tempted Americans to embark on a policy of exploitation concurrently with expansion has gone, in certain spheres retreat has followed expansion and many rueful surveys are being made of what has been left, with sound suggestions as to how it may best be used for the future America wants to reverse the processes by which man has violated basic arrangements in a manner which Nature will not tolerate" The literature covers a wide range of subjects, including land use which in this continent is especially bound up with the subject of soil erosion forestry and afforestation, important not merely because 'almost every one of the forty eight states is headed towards forest bankruptcy in timber but also because deforestation has had a terrible sequel in floods, soil wastage and silted rivers Lists of books on Oil and Gas Conservation and Saving Our minerals indicate that the future shortage of these vital products has passed from the realm of prophecy to that of serious and calculable prediction The inclusion of a section on the conservation of wild life serves to show how important is this question both in and out of the national parks which are of increasing value to the States

Research at Port Erin, Isle of Man

THE report of 1937 (No 50) of the Marine Biological Station at Port Erin, Isle of Man drawn up by Dr R J Daniel, director, shows the largest number of students using the building in any one year and also the greatest number of visitors to the aquarium More plaice larvæ have been liberated than during any previous season and there has been the highest percentage survival of lobsterlings in the hatchery The new Fauna List is now published a most useful and complete volume—which will be of the greatest assistance to all students The main work of the Laboratory has been directed towards the breeding of oysters a research which has now been going on for more than three years The chief difficulty in obtaining proper spatfalls in the experimental pond is the varying temperature—a very low temperature ruining a promising beginning To combat such conditions, a number of oysters were kept at a raised temperature level in the culture house Some oysters were also kept in dishes in the hatchery and the spawn from these has provided the basis for the limited series of culture house experiments These are still going on, and work is maintained in the improvement of methods and feeding of the larvæ in specially adapted vessels

Announcements

SIR WILLIAM BRAGG has been elected a foreign associate of the Paris Academy of Sciences in succession to the late L Torres Quevedo

PROF MAJOR GREENWOOD, professor of epidemiology and vital statistics in the University of London, has been awarded the Bisset Hawkins Gold Medal of the Royal College of Physicians, for his researches in statistics

THE twelfth International Horticultural Congress will be held in Berlin on August 12–20 After a series of meetings in Berlin the delegates will visit certain horticultural experimental stations and the chief areas of horticultural production A visit on August 20 to a Horticultural Exhibition at Essen will bring the Congress to an end The following delegation has been chosen to represent the British Government at the Congress Mr H V Taylor, Mr David Akenhead Prof E E Cheeseman, Mr F Birkinshaw, Mr F J Chittenden Col I R Durham Dr R G Hatton Sir Arthur Hill Mr H J Holman, Sir Frank Stockdale Dr M A H Tincker and Dr C W Wardlaw

A General Discussion on Luminescence has been arranged by the Faraday Society and will be held in the Biochemical Laboratory University of Oxford on September 15 17 Among the topics to be discussed are various aspects of the luminescence of solids liquids and gases and chemiluminescence As usual in these discussions a number of distinguished foreign guests have been invited to take part

THE Council of the Harveian Society of London has chosen The Value of Periodic Medical Examination in the Detection of Disease in Middle Life" as the subject for the Buxton Browne Prize, which consists of a medal and a sum of £100 The prize is open to any member of the medical profession registered in the British Isles or Dominions, and is limited to candidates less than forty five years of age Essays must be sent to the Treasurer of the Society Mr Cecil Wakeley, 14 Devonshire Street W 1 before October 1 1939

MR ROBERT L SACKETT dean of the School of Engineering at Pennsylvania State College from 1915 until 1937 has been awarded the Lamme Medal of the Society for the Promotion of Engineering Education for achievement in this technical field Mr Sackett is the eleventh recipient of the medal provided for in a trust fund created by the late Benjamin Garver Lamme who was chief engineer of the Westinghouse Electric and Manufacturing Co for twenty one years prior to his death in 1924 Since his retirement as dean at Pennsylvania State College, Mr Sackett has devoted himself largely to the work of the Engineering Council for Professional Development He has served as president of the Society for the Promotion of Engineering Education and as vice president of the American Society of Mechanical Engineers

ERRATUM In the letter entitled 'Irregular Mitosis and Meiosis induced by Acenaphthene" by Prof Dontcho Kostoff, in NATURE of June 25, p 1144, the sentence beginning "The viable pollen grains are equal in size " should read "The viable pollen grains are unequal in size "

Letters to the Editor

Optical Observation of the Debye Heat Waves in Crystals

MANY years ago[1], it was pointed out by one of us that Debye's concept identifying the thermal energy of a solid with the energy of elastic vibrations within it having a wide range of frequencies has an important optical consequence, namely, that a beam of light traversing a transparent solid would be scattered to an extent depending upon the energy of thermal agitation This conclusion was also verified experimentally in a semi-quantitative fashion[2] The principal experimental difficulty in studying the subject was that of obtaining crystals sufficiently large and at the same time free from imperfections or inclusions, these conditions being necessary to prevent the feeble thermal opalescence being overpowered by parasitic diffuse light The same difficulty appears in attempting to investigate the thermal opalescence in crystals by spectroscopic methods. The elastic waves, longitudinal or transverse as the case may be, which scatter the light being progressive, they should give rise to Brillouin-Doppler shifts of optical frequency corresponding to their respective acoustic velocities. If parasitic light be present, the unmodified scattering and the hyperfine structure components usually accompanying the same would overpower the Brillouin-Doppler components to be expected.

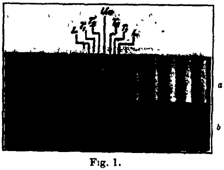

Fig. 1.

(a) DIRECT LIGHT, (b) SCATTERED LIGHT

It is significant, in view of the foregoing remarks, that E. Gross[3], who claimed, some years ago, to have obtained evidence of a Doppler shift due to the longitudinal waves in crystals, offered neither photographs nor measurements confirmatory of the claim. Even in a recent communication[4] in which the same author points out that with crystals there should be three components on either side in the scattered light corresponding to the three sheets of the acoustic wave-surface, no such convincing experimental evidence has been presented. Indeed, a perusal of the communications quoted leaves the impression that the results so far obtained by E. Gross suggest, rather than demonstrate, the existence of such Brillouin-Doppler shifts in the light scattered by crystals

The thermal scattering of light in crystals has been under investigation in this laboratory during the past few years, and we have at last succeeded in obtaining satisfactory photographs which show in an unmistakable way the physical reality of the Debye heat waves in crystals Fig 1 (*a*) shows the interference pattern taken with a Lummer Gehrcke plate of 4046 A radiation of a water cooled mercury lamp Fig. 1 (*b*) shows the pattern, under exactly the same conditions, of this radiation scattered transversely within a large crystal of gypsum The latter had been previously examined in a strong beam of sunlight, and a portion which showed a clear blue thermal opalescence and was free from inclusions was chosen for illumination. On a comparison of the two pictures which have been carefully set side by side to correspond, it will be seen that the two patterns are completely different Measurements show that the principal component of the incident radiation, which is very feebly present in the scattered light, gives rise to three components on either side displaced by 0·59, 0·36 and 0 2 cm $^{-1}$ of which the first is the most intense From the Brillouin formula, these three shifts correspond respectively to acoustic velocities 3,350, 2,050 and 1,100 metres per second. Of these, the first is presumably due to the longitudinal waves and the other two due to the transverse ones

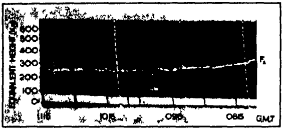
Bright Solar Eruptions and the Ionosphere

AN investigation of the ionospheric conditions during a bright solar eruption shows that at such times an increase of ionization can be produced within the normally reflecting regions of the ionosphere.

The accompanying photograph shows such an increase of ionization to have occurred quite suddenly at 0927 G.M.T. on October 1, 1937, at an equivalent height of 125 km., or slightly higher than the normal *E* region. A solar eruption of intensity 1 reported from the Royal Observatory, Greenwich, to have begun at 0928 G M T was, we suggest, the cause of this burst of ionization, which increased the normal amount in this region by more than 100 per cent The photograph shows a second reflection from this height of 125 km, indicating that no marked absorption in or below the normal *E* region was produced during the eruption These observations indicate that the quality of the ionosphere for the propagation of radio waves is sometimes improved as the result of a bright solar eruption



IONOSPHERIC DISTURBANCE BEGINNING AT 0927 G M T ON OCTOBER 1 1937

It is now well known[1] that there have been an increasing number of occasions during the last few years when during a bright solar eruption radio signals have disappeared completely At such times the condition of the ionosphere is similar to that described in 1933[2] as the no echo condition and is due to the production of ionization at abnormally low levels the consequent absorption thereby masking the normal reflecting regions

We deduce therefore that on a majority of occasions on which bright solar eruptions take place ionization is produced in the ionosphere, and that it depends primarily upon the *height* at which it is produced whether radio transmission conditions are better or worse It follows therefore that the initial comparisons of the worst radio transmission conditions and bright solar eruptions must be extended to include this more recent observation before the effects of a bright solar eruption on the ionosphere can be completely assessed

The work described above was carried out as part of the programme of the Radio Research Board and this note is published by permission of the Department of Scientific and Industrial Research

Crystal Structure Models

TABLE tennis balls have often been used in making models of crystal structures, and the purpose of this letter is to direct attention to two ways of using them which, so far as we are aware, are new

(1) Models of crystal structures of inorganic substances are clearest when the atomic centres are indicated by balls and these are joined by rods The following method may be used to connect table tennis balls by rods of celluloid, a convenient diameter for which has been found to be 3/16 in The end of the rod are dipped in acetone for about a minute when they swell and become gelatinous on the surface Meanwhile, the surfaces of the balls to be joined are rendered slightly gelatinous by moistening them with acetone The rod is now placed in position between the balls and if necessary held there for about 20 sec The rod and balls now adhere to one another sufficiently strongly for it to be possible to continue building the model Durofix may be used as the cement but the join is not so strong as that obtained with acetone Celluloid rods can be easily cut to any required length and this greatly facilitates the making of models with correct interatomic distances

(2) In studying the structures of organic substances, *it is often necessary to see how molecules* pack into the unit cell The distance between neighbouring carbon atoms in a molecule is about 1 5 A while the distance between carbon atoms in neighbouring molecules is not usually less than 3 4 A A model representing the space occupied by any one molecule can therefore be made by cutting off spherical caps from the table tennis balls and fitting the balls together so that the distance between their centres is ¾ in Such model molecules can then be packed into the unit cell with their surfaces touching To cut off the spherical caps the balls are held in a split brass tube of internal diameter slightly less than 1½ *in* mounted on a lathe and a razor blade is used as a cutting tool

The accompanying photographs show similarly orientated models of naphthalene $C_{10}H_{14}$ constructed according to both methods The model with rods is valuable in teaching and the packing model is more useful in research work when it is required to discover the geometrically possible molecular orientations

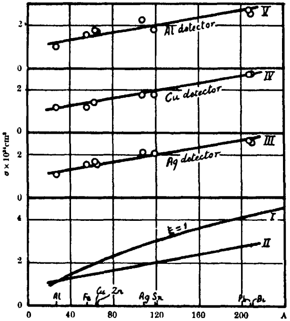
Interaction of Fast Neutrons with Atomic Nuclei

Neutrons may interact with nuclei in two different ways, namely (*a*) formation of a compound nucleus, in a quasi-stationary state, with a subsequent emission of a corpuscular or electromagnetic radiation; (*b*) elastic (possibly also inelastic) collisions without sticking to the nucleus.

The decrease of intensity of a fast neutron beam when passing through matter, measured with a detector which responds only to neutrons above a certain energy, will be due to inelastic collisions (mostly process *a*) and elastic scattering (mostly process *b*)

The aim of this work was the study of the interaction of fast neutrons with nuclei through the measurement of the neutron absorption in different substances



I produced the neutrons by deuteron bombardment of lithium (400 kv, about 100 μ amp), as a measure of their intensity I used the activities induced by reactions of the type ($n - 2n$) and ($n - p$), that is, such reactions as $^{107}\text{Ag}\text{-}n\text{-}2n\text{-}^{106}\text{Ag}$ (24·5 min.), $^{63}\text{Cu}\text{-}n\text{-}2n\text{-}^{62}\text{Cu}$ (10·5 min) and $^{27}\text{Al}\text{-}n\text{-}p\text{-}^{27}\text{Mg}$ (10·2 min.). The energy of the neutrons has in these conditions an upper limit of about 13·5 Mev.[1]. The detectors respond only to high-speed neutrons: silver and copper to neutrons of energies certainly above 8 Mev. and probably practically 12 Mev. (at least for copper[2]), aluminium above 4·5 Mev. Thus my measurements concern two energy regions of very different widths: 12–13·5 Mev. and 4·5–13·5 Mev

The absorbing substances and the detectors were placed in the immediate neighbourhood of the neutron source; thus a great part of the scattered neutrons were reaching the detector and therefore the extinction of the beam was mostly due to effects other than scattering. If we suppose that every neutron that sticks to a nucleus and forms with it a compound nucleus cannot produce any of the above-mentioned reactions in the detector, then, in these conditions, the effective cross-section of the absorbing nucleus, as calculated from the intensity measurements, should not be smaller than $\sigma = \pi R^2 \xi$ where ξ is the sticking probability (process *a*) and R the nuclear radius. Curve I gives the calculated values of σ for different atomic weights A, assuming $\xi = 1$ and $R = 2 \times 10^{-13} A^{1/3}$ cm.

Measured cross sections for silver, copper and aluminium detectors are plotted as Curves III, IV, V, and the average for all detectors as Curve II

The discrepancy for heavy nuclei between the experimental Curve II and the theoretical Curve I can be explained by assuming that for these nuclei, ξ is less than 1, that is, a fast neutron may fall on a nucleus without sticking to it and without changing its direction by a great amount.

Another possible explanation would be to suppose that ξ equals 1, but to assume that compound nuclei are able to emit neutrons still of sufficient energy to activate the detectors; in this case we should be dealing either with elastic scattering or with scattering in which the neutron suffers quite a small loss of energy However, due to the difference in the width of the sensitivity regions of the detectors, it is to be noted that this assumption would lead to a greater cross-section as detected with silver and copper than with aluminium This is not the case and, on the other hand, an emission of very fast neutrons by compound nuclei, though highly excited, is very improbable, if we assume the liquid drop model

The former assumption (ξ less than 1) seems to fit experimental data and theoretical expectations better. It is interesting to note that the experiments of Dunning, Pegram, Fink and Mitchell[3] in which, contrary to my experimental conditions, the authors measured the absorption including all processes mentioned above (*a* and *b*) the curve $\sigma(A)$ has a shape corresponding rather to the assumption that ξ equals 1

After this work was completed, Grahame and Seaborg[4] published a paper on a similar subject. My results, though concerning neutrons of somewhat different energy regions, are in excellent agreement with theirs.

A detailed description of the apparatus and the experimental arrangement used will be published elsewhere.

I wish to express my thanks to Prof. S Pieńkowski for many stimulating discussions.

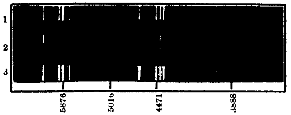
Band Spectrum of Helium

In the course of some investigations on the electrical properties of helium at fairly high pressures (about 25 mm. mercury), it was found that, if the gas was excited in such a way as to produce the line spectrum and the band spectrum of helium in comparable intensity, the rate of decrease in intensity of the band spectrum was much smaller than that of the line spectrum after the excitation was removed.

The accompanying reproduction shows three spectra of a discharge in helium at 27·5 mm. pressure taken under different conditions with a Bellingham and Stanley No. 2 glass spectrograph. Spectrum 1 was taken when the discharge was running continuously. Spectrum 2 was taken of a discharge in which the excitation was interrupted periodically and in which the light from the discharge could fall on the spectrograph about 1/600 sec after the excitation was interrupted. Spectrum 3 was taken with an interrupted discharge in which the light from the discharge was able to fall on the spectrograph just before the excitation was interrupted.



BAND SPECTRUM OF HELIUM (2·75 MM MERCURY)

It will be seen that, for comparable intensities of these band spectra the intensity of the lines in spectrum 2 is negligible compared with that of the lines in the spectra 1 and 3. As the energy of the electrons in the discharge is insufficient 1/600 sec after the discharge has been interrupted, to excite the atoms of helium, it seems necessary to suppose either that the helium molecule is formed after interruption of the discharge by the collision of a metastable atom with a neutral atom or that the helium molecules formed in the discharge have a life of the order of 1/600 sec. As the rate of decrease in intensity of the band spectrum is of the same order as the rate of decrease in number of metastable atoms the former explanation seems the more probable.

Reflecting Power of Crystals with an Ideal Mosaic

WE have studied photographically the connexion between the magnitude of the mosaic structure of crystals, $\Delta\sigma$, and the intensity of X-ray reflection, R_s, in a symmetrical arrangement, in which the radiation by the mosaic crystals is focused[1].

As has been shown by Feifer and Jahoda by means of a double crystal spectrometer with photographic recording[2], there are two kinds of mosaic, namely, a normal regular 'ideal mosaic' ($\Delta\sigma_{min}$) and a coarse, less regular, the latter occurring in imperfect and especially in metallic crystals. This irregular mosaic causes sometimes a considerable increase of the value of $\Delta\sigma_{min}$.

The experiments have shown that the reflecting power of X-rays varies with the magnitude of the mosaic $\Delta\sigma_{min}$, and that in the case of crystals with a large ideal mosaic, its influence on the intensity of reflection R_s predominates over the other factors (distribution of electrons, absorption in the lattice and so on). The following relation has been found to hold:

$$\frac{f(\Delta\sigma_{min})}{R_s} = \text{constant}$$

When investigating the reflecting planes of crystals by Baćkovský's method, it is found that separate parts of the crystal are considerably imperfect, whereas some parts do not reflect at all. Thus an exact relationship can only be obtained by the use of especially selected crystals. As an example of our measurements with different crystals—quartz, gypsum, rock salt and sphalerite—we have discussed measurements in which the coefficient of reflection is characterized by the exposure $T_s \sim 1/R_s$ (in a symmetrical arrangement for the copper K lines) under identical conditions.

Crystal	$\Delta\sigma_{min}$. 10 (rad.)	T_s. 10 (sec.)	$\Delta\sigma_{min}$. T_s. $10^4 \sim \frac{\Delta\sigma_{min}}{R}$
SiO₂ ⊥ axis	(4·8)	{36·0 0·0}	{1·7 3·3}
CaSO₄	10·4	2·4	2·3
NaCl	8·8	0	2·0
ZnS	56·2	3·6	2·0

From the third column of the table it is evident that the product of the exposure and the magnitude of the ideal mosaic is constant, that is,

$$T_s \cdot \Delta\sigma_{min} = \text{constant}$$

Only in the case of quartz, where the mosaic is insignificant, do the results fluctuate. The coarse mosaic of the imperfect crystals of metallic type does not contribute to the intensity of reflection.

We wish to mention that under the influence of a direct electric field (of about 10,000 volts/cm.) we obtained for ZnS a diminution of the mosaic $\Delta\sigma_{min}$ from 110″ to 80″. This change became after a longer application of tension permanent (plastic). The diminution of the mosaic was accompanied by the diminution of the intensity of reflection. Since in the case of rock salt no analogous case was observed, the rectification of the mosaic of sphalerite is probably due to the piezo electric forces.

The changes in the mosaic exhibited by grinding depend mainly on the kind of grinding.

The large intensity of reflection of crystals with an ideal mosaic justifies their utilization in all symmetrical methods.

Films on Freshly Abraded Copper Surfaces

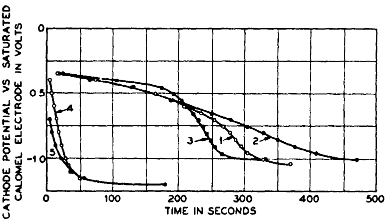
WE have been interested in the nature and amount of films formed on metals during and immediately after cleaning by abrasion, and have made measurements of the thickness of such films using a modification of the electrolytic method of Evans and Miley[1]. We find that films of substantially the same thickness, giving similar cathode potential time curves at constant current, are present on freshly abraded copper whether the abrasion is carried out in air or under benzene. A somewhat thinner film was found when an abrasive wet with water was used. The results are summarized in the accompanying table, the figures in the third and fourth columns representing the means of at least three determinations for experiments 1–3 and of two determinations for experiments 4 and 5 Typical curves are given in the accompanying figure

THICKNESS OF FILMS ON FRESHLY ABRADED COPPER SURFACES

Experiment No	Treatment of surface	Milli equivalents of film reduced* per sq cm 1)	Thickness of film as Cu_2O*(A
1	Abraded 000 emery paper under benzene	3 2	41
2	Abraded 000 emery paper in air	3 9	4
3	Abraded 000 emery powder under water	2 8	33
4	Abraded 000 emery paper reduced in hydrogen	No detectable film	
5	Abraded 000 emery paper reduced in hydrogen immersed in benzene 20 mins	0 16	2

* Area of surface calculated from measured dimensions

The edges and both faces of the specimens which were milled to 2 cm × 2 cm × 0 2 cm from oxygen free high conductivity copper were abraded Abrasion under benzene was carried out in a very similar manner to that described by Dobinski[2] The benzene was a high quality thiophene free grade which had been twice redistilled over activated copper The specimens were placed wet in the electrolytic cell and were dried in a stream of purified nitrogen The cathode potential measurements were made in an oxygen free solution over which nitrogen was passed



CATHODE REDUCTION OF FILMS ON FRESHLY ABRADED COPPER

Current density 0 01 ma /sq cm area of surface 9 6 sq cm Arrows indicate inflection point Numbers refer to accompanying table

Recently Dobinski[2] has shown that the electron diffraction pattern obtained for a metal polished under benzene is different from that for a metal polished in air and has inferred that the pattern is characteristic of an unoxidized surface The experiments reported here show that abrasion of copper surfaces under benzene by a very similar technique produces a surface film probably oxide which is comparable in thickness to that produced by abrasion in air Submersion of copper in benzene without abrasion produces a considerably thinner film Dobinski assumes that polishing under benzene means polishing in the absence of air Actually the solubility of oxygen in benzene is appreciable[4] He also believes that polishing with a moist abrasive in air produces a thicker film than polishing with a dry abrasive Our experiments indicate that this is not the case when copper is abraded with emery

Our results may be explained on the assumption that combination of the copper takes place with oxygen dissolved in the benzene or the water at the high local transient temperatures developed on the surface during abrasion[3] More detailed results and experimental technique will be published shortly

Electron-Inertia Effects in Thermionic Tubes

I WAS extremely interested in the communication by Messrs Ratcliffe and Kownacki[1] on the investigation of electron inertia effects in thermionic tubes As these writers state the difficulty in the experimental determination of inertia effects in ordinary valves is that they occur at such high frequencies that accurate measurement is practically impossible In order to increase the inter-electrode transit time and so decrease the frequency at which the inertia effects become appreciable Messrs Ratcliffe and Kownacki propose using a thermionic tube in which the electrons are replaced by relatively slowly moving ions

I have described[2] an alternative way by which the inertia effects may be made to occur at sufficiently low frequencies for accurate measurement The inter electrode transit time of electrons in a cylindrical diode can be increased many times if a magnetic field of suitable magnitude is applied to the valve in the direction of the electrode axis I have investigated experimentally the effect of these long transit times and have determined the equivalent electrical circuit of any thermionic tube in which the inter electrode transit time of electrons is predominant I have shown that the long transit times possible in magnetrons are responsible for the production in these valves of relatively low frequency oscillations similar in character to the high frequency Barkhausen Kurz oscillations generated in positive grid triodes It would be interesting to know whether Messrs Ratcliffe and Kownacki obtain the same results for inertia effect with their novel type of triode as I have with the magnetron

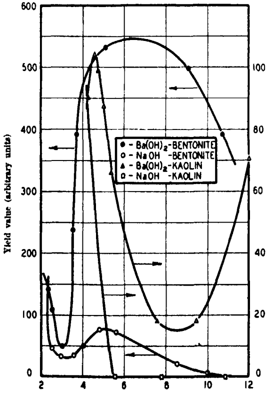
Viscosity of Clay Suspensions

Considerable attention has been given recently to the thixotropy and viscosity characteristics of clays. During the course of a research programme now in progress, certain results of general interest have been obtained

Fract No	Average equivalent spherical diameter	Mobility 25° C	(cp ¹ 50° C)	Yield Value (dynes/cm ²)		r (25° C)
				25° C	50° C	
1	0 135 μ	0 580	—	34 5	—	1 93
2	0 28	0 625	1 64	22 6	32 0	1 79
3	0 45	0 862	—	0		1 30
4	1 05	0 950	—	0		1 18
5	0 55	0 950	—	0		1 18
6	2 2	0 991	2 94	0	0	1 13
7	8 5	0 991	-	0	—	1 13
2 (in 40 2 wt % ethyl alcohol	0 28	0 276	2 14	69 5	48	1 52

Viscosity measurements, using a capillary viscosimeter (radius 0 0415 cm , length 9·33 cm) were made upon seven samples of kaolinite of varying particle size, kindly supplied by Dr H Whittaker from fractionation of Kentucky ball clay (fractions 1-4) and Georgia kaolin (fractions 5-7). X-ray analysis indicated all to be essentially kaolinite, except fraction 4, which contained about 30 per cent silica The results for suspensions of 10 weight per cent are shown in the accompanying table, pH being approximately constant at 6 5



Deviation from normal behaviour, as indicated by yield value and relative viscosity at infinite shear, increases with decreasing particle size and was found to parallel plasticity. Rise in temperature caused an increase of yield value for aqueous suspensions, in contradiction of predictions[1] made on the basis of the attraction-repulsive force theory of Hamaker[2] Alcoholic dispersions, however, showed a diminution in yield value with temperature, as did glass spheres suspended in an organic liquid and measured by a technique previously described[3].

The accompanying graph shows results obtained, using a MacMichael viscosimeter, when varying amounts of caustic soda and barium hydroxide were added to electro-dialysed kaolin and bentonite suspensions The suspensions containing caustic soda showed little or no thixotropy, but it was very pronounced for barium hydroxide - bentonite suspensions from about pH 4 upwards. The results indicate the importance of the nature of the metallic ions associated with a clay and suggest that the presence of certain ions may be essential for thixotropy.

Complete data will be published elsewhere.

Estimating Numbers Without Counting

In ecological work it is often necessary to have comparative estimates of the numbers of organisms in a large number of samples An exact valuation may not be required, but an approximate numerical estimate is always preferable to statements in such terms as few, many, very many, etc The following method was devised to furnish estimates rapidly and without counting of the numbers of a few of the more important species of the marine plankton where only one or two such species formed the bulk of the samples and *where an estimation within ± 15 per cent of the actual numbers would be sufficient.* Actually the plankton is as a rule so mixed that the method can only be applied to special series of samples and not to normal survey work. It is thought, however, that the method, which is believed to be new, may be of value to workers in other fields · perhaps for estimating the seed production of a large number of plants or samples of small insects all of one species.

The method is akin to the colorimetric method and the name proposed for it is the *plethometric method* (πλῆθος: an aggregation or multitude), kindly suggested by my colleague, Prof. T. E Jessop.

A scale of dots is made as in Fig 1 The dots are so arranged that when a mask with a circular opening is placed over the scale, the number visible will increase by a definite amount as the mask is slid from left to right. At *A* the number visible is 110, at *B* it is 230 and at *C* it is 270. From such a scale others can be made having, instead of dots, life-size photographic images of the objects to be estimated. A strip of glass coated with glycerine jelly is laid upon the original scale and one of the objects dropped into position over each dot, and then the whole is photographed and enlarged to natural size. Scales for common plankton animals such as *Calanus*, *Sagitta* and *Limacina* were very skilfully made for me by Mr J H Fraser when a member of my staff Such scales are mounted in a frame to wind off one roller on to another below a circular opening as in Fig 2, the rollers being turned at X and Y Along side is placed the sample in a circular dish of the same size as the said opening and the sample is spread as evenly as possible by a needle or brush The scale is turned to right or left until its number of images appears to equal that of the objects in the sample, with practice this may be done very quickly and usually to within ± 10 per cent The number is read off through the opening *n* which may be kept screened by the slide *s* until the judgment is made When once such a scale is made hundreds of samples can be dealt with in a very short time Even without a photographic scale a scale of dots roughly the size of the objects in the sample will serve for providing an approximate estimation

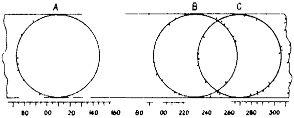

Fig 1

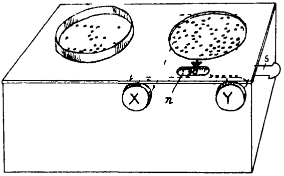

Fig 2

My friend, Dr E O Halliwell, has suggested that it might be applied to the rapid estimation of blood corpuscles in place of the usual counts A double microscope with a single but divided eyepiece would enable one to compare a blood sample with a photographic scale or a slide of increasing numbers of actual corpuscles prepared as a permanent mount Experiments we have made using two microscopes and a comparator eyepiece indicate that it should be as accurate as the use of the ruled counting slide, and very much quicker

Assignment of the Fundamental Frequencies and Computation of the Potential Function of Tetrachlorethylene

The vibration spectrum of tetrachlorethylene has been discussed by me[1] and later by Linnett and Thompson[2] It is of particular interest in that the value for the C—C force constant ($6\ 25 \times 10^5$ dynes/cm) seemed abnormally low for a double bond This was taken to indicate resonance between other possible structures in which the carbon atoms were linked by a single bond

In both the above investigations a simplified type of potential function was employed in which many interaction terms were ignored The importance of those terms has since been demonstrated by the work of Manneback[3] and others[4] on the spectrum of C_2D_4 I have therefore undertaken a re investigation of the spectrum of C_2Cl_4 using a potential function of the type employed by Manneback and Verleysen[3]

Assuming for the nine planar frequencies of the molecule the values (in Manneback s notation) S_1 (1569 445 383) A_1 (913 400*) A_2 (802 346*) S_2 (512 341) a thirteen constant potential function is necessary to obtain real solutions in the four groups I have attempted to approach as much as possible the valency deformation system nevertheless the values of interaction constants are very important (20 per cent of the principal terms) so demonstrating the great influence of Cl atoms

The detailed result cannot be quoted here, but it is sufficient to remark that the value for the C—C force constant is now 8×10^5 dynes/cm instead of $6\ 25 \times 10^5$ It would therefore appear that the earlier conclusions regarding the existence of resonance in this molecule may be premature since it is possible to correlate the frequencies with a force field in which the C—C constant has its normal double bond value

The other important point to which I would direct attention concerns the assignment of the fundamentals where it will be noticed that the value for the lowest of the S_1 group is taken as 383 cm $^{-1}$ instead of 236 cm $^{-1}$ which represents a motion out of the plane This is based on the polarization measurements of Heidenreich[5] The above set of fundamentals allows of easy interpretation of the remaining observed frequencies as simple addition bands

Detailed calculations and discussion will appear shortly elsewhere

Distribution of Fluorescence Excitation of Bivalent Europium in Calcium Fluoride and of Bivalent Samarium in Calcium Sulphate

In the course of the investigation of the fluorescence of fluorite conducted in the Institut für Radiumforschung, Vienna[1], it seemed desirable to determine the distribution of excitation in fluorite for the blue Eu^{++} band

A series of limited portions of the ultra violet spectrum of an iron arc was successively allowed to fall on the powdered sample in a flattened quartz test tube The blue fluorescence thus excited was photographed on different parts of a Kodak Panatomic film behind a filter to keep out the ultra violet light The transparency of the developed film was measured with a barrier layer photo cell Taking into account the energy distribution in the spectrum of the iron arc, maxima of the blue fluorescence were found for the following wave lengths of the exciting light for synthetic calcium fluoride with 10^{-3} or 10^{-4} europium and in sodium chloride with 10^{-4} europium, all after treatment with radium rays from 230 to 240 mμ 260 280 350 and 385 mμ, for natural fluorite from Weardale (purple) practically the same wave lengths, only, instead of the last mentioned maximum one at 400 mμ[2] For longer wave lengths the method is not applicable because of the overlapping of exciting and emitted wave lengths

Calcium sulphate with 10^{-3} samarium gives after radium treatment for the red Sm^{++} fluorescence maxima of excitation at 240 350 370 and 400 mμ Treatment of calcium sulphate with 10^{-3} samarium with light of wave length 240 mμ has the same effect as that with radium rays the untreated preparation shows, when illuminated with filtered ultra violet light, only the well known lines of trivalent samarium, but after prolonged treatment with wave length 240 mμ, the red and infra red bands 630 and from 689 mμ to 734 mμ appear on illumination with filtered ultra violet In calcium fluoride with europium also the wave length 240 mμ seems to produce the same effect as radium rays

Presumably the excitation maxima of shorter wave length are connected with the *formation* of excited bivalent rare earth centres (reduction of the trivalent rare earth ions), those of longer wave length with the excitation of such centres already formed

Crystal Structure of Thianthren and Selenanthren

IN a recent paper by Cullinane and Plummer[1] on the isomorphous relationships of some analogous organic derivatives of oxygen, sulphur and selenium, we gave the results of some preliminary crystallographic measurements on thianthren and selenanthren (diphenylene disulphide and diphenylene diselenide) The crystallographic measurements have now been completed and an X ray determination made of the sizes of the unit cells The results are here given and refer to a different c axis from that quoted in the paper by Cullinane and Plummer

The crystallographic measurements show that thianthren and selenanthren, which crystallize in the monoclinic system, are isomorphous This result is in agreement with the conclusions of Cullinane and Plummer Our observations also show that the unit cell for thianthren chosen by Prasad, Shanker and Peermohamed[2] is face centred in the basal plane and is therefore not primitive This agrees with the remark to that effect made by Cox[3] Our photographs confirm the assignment of the space group C_{2h}^5 to thianthren made by Prasad, Shanker and Peermohamed and show that selenanthren also belongs to the same space group

Full details of the work will be published elsewhere

Colchicine and Acenaphthene as Polyploidizing Agents

KOSTOFF[1] has recently directed attention to the similarity in action of colchicine and acenaphthene and recommended the latter substance for purposes of chromosome doubling Preliminary tests with acenaphthene used in saturated solutions of liquid media[2] adapted to the observation of mitosis in stamen hairs of *Tradescantia* gave no indication that acenaphthene is at all comparable to colchicine as a polyploidizing agent After 2 and 4½ hours counts of nuclear stages showed the following percentages

	Prophases	Prometa-anaphases	Telophases	
Acenaphthene	9	3	-	2 hours 200 cells
Check	11 8	4	9	
Acenaphthene	9 4	1 9		4½ hours 100 cells
Check	9	1 6	9 6	

Not a single polyploid cell was formed in this experiment nor were any nuclei observed showing chromosomes in metaphasic condition typical of colchicine Young plants of marigold tops of which were immersed for 1 48 hours in culture solution[2] saturated with acenaphthene showed during the successive week effects distinct from those of colchicine

Kostoff[3] has meanwhile changed his method of application of acenaphthene Instead of using saturated solution he now brings crystal into contact with the plant material Certain phases of the acenaphthene reaction apparently resemble that of colchicine More work is required before the effects can be compared Any reversible reaction of the type described by Kostoff, if easily applied widens the possibilities of inducing somatic changes in clonally reproducible plants

Effects of Floods in East Norfolk

A RECENT visit to the part of East Norfolk flooded by the sea in February and April of this year was made memorable by a succession of south westerly gales towards the end of June The best point from which to see the flood damage was found to be at Horsey Staithe Looking north eastwards an astonishing spectacle met the eye To the left there was a summer scene of woods and cottages clustered round Horsey Hall and Horsey Church, where a slight elevation of the ground had left an island during the advance of the sea In front the sea's retreat had left a red desert towards which the gale raced during the forenoon and early afternoon when the local land breeze reinforced it, a region later to be haunted by the melancholy piping of redshanks and the anxious cries of a cloud of lesser terns and ringed plover, when there came the calm of the evening before the setting in of the prevailing south east breeze This red desert, so recently part of the North Sea, ended in an imposing greyish yellow barrier where the sand dunes were being rebuilt with the aid of a crane fed by a hastily constructed light railway

During the worst of the gales, that of June 20, smoke was seen, rising apparently from one end of the barrier itself What could be burning up there on that barren sand ? In a few moments the mystery was solved, a steamer appeared, its funnel visible almost down to deck level This was no mirage, but evidence that it was high tide and that if the gale were to veer to north west the scouring undertow would soon resume its work of destruction But the people of the village showed no signs of fear even during the height of the gale, for they retain unspoiled, many of them, the hardy spirit of the men who used to set out from Denmark in mid winter for Iceland or Greenland in open boats and often arrived at their destination To the Londoner or foreigner as he is termed by the Broadsmen, Horsey Staithe did not seem to be a place in which to linger on that June morning

Leaving the ruined bird sanctuary on the southern side of Horsey Mere to one s left and taking a path which leads past sledge covered shallows, where the bittern can still be found to Waxham Cut, the scene began to change An arm of the red desert on the right presented a more than wintry landscape, the nearer trees were rust red and more gaunt than trees in their winter sleep, but on the banks of the Cut bright green sedge was springing up On the calmer days earlier in the month, reed buntings were to be seen as usual, and many swallow tail butter flies

The old farm house by the bridge, where so many bird lovers have gathered during the past five years, luckily escaped the flood with a few scars only Some of the trees had sucked up the brackish water and assumed the rust red of the neighbouring plain, but others were in their summer green From this point to Waxham village and Palling the countryside had its usual summer appearance apart from the effects of the drought of the previous four months Only the presence of workmen strengthening and renewing the dunes at Palling gave a hint as to where the next assault of the sea might be expected, while the large and now rarely used parish church at Waxham was a reminder that the sea s advance has in the course of centuries swallowed up miles of once prosperous countryside

Highgate

Points from Foregoing Letters

PHOTOGRAPHS showing the interference pattern of light scattered by thermal agitation (elastic weights) in a clear crystal of gypsum are submitted by Sir C V Raman and C S Venkateswaran The displacement of the three components into which the incidental radiation is split indicates, according to Brillouin s formula, acoustic wave velocities of 3 350, 2,050 and 1,100 m per sec

A hundredfold increase in the ionization at an equivalent height of 125 km, slightly higher than the normal *E* region, which occurred on October 1, 1937, at 0927 G M T is ascribed by R Naismith and W J G Beynon to a bright solar eruption the appearance of which was reported by the Greenwich Observatory at practically the same time

Dr A Soltan has measured the effective cross section for collisions of fast neutrons with atomic nuclei The sticking probability appears to be less than unity, at least for heavy nuclei

From the persistence and rate of decrease in intensity of the band spectrum of helium gas (at 25 mm mercury pressure) Dr S P McCallum and M S Wills infer that either the helium molecules formed in the electric discharge have a life of the order of 1/600 sec or, more probably, they are formed after interruption of the discharge by the collision of a metastable atom with a neutral atom

A photographic study of the relations between the magnitude of the mosaic structure of crystals and the intensity of X ray reflection shows, according to Prof V Dolejšek, M Jahoda, J Ježek and M Rozsival, that the case of specially selected crystals of calcium sulphate, sodium chloride and zinc sulphide, the product of the exposure and the magnitude of the ideal mosaic is constant

Using an electrolytic reduction technique W E Campbell and U B Thomas show that films 30–60 A thick as oxide, are formed on copper during abrasion by French emery, whether carried out in air, under benzene or under water

Commenting on Ratcliffe and Kownacki's suggestion to utilize slowly moving ions in place of electrons in a thermionic tube, in order to decrease the frequency at which inertia effects become appreciable, Dr J S McPetrie refers to an alternative method in which a magnetic field of suitable magnitude is applied to the valve in the direction of the electrode axis

A table giving the mobility and other properties of kaolin clays of known particle size, and graphs showing the effect of *p*H and valency of cations upon the yield value of aqueous suspensions of such clays, are submitted by G Broughton and R S Hand

A method of rapidly estimating within about fifteen per cent the number of small organisms, seeds, etc, in samples, by comparison with a photographic scale of equal size dots or objects, of known density, is described by Prof A C Hardy

A reinvestigation of the spectrum of tetrachlorethylene, C_2Cl_4, using a potential function of the type employed by Manneback and Verleysen, leads J Duchesne to a value of 8×10^5 for the C—C force constant instead of $6 25 \times 10^5$, so that the frequencies can be correlated with a force field in which the C—C constant has its normal double bond value

Research Items

Property among the Ciga of Uganda

THE Ciga of Uganda and Ruanda, whose system of property holding has been studied by Miss May Mandelbaum Edel (*Africa*, 11, 3, 1938), unlike most people of this area, were not ruled by Hamitic overlords and when British dominion was established over them were independent. The basis of their livelihood is horticulture, the fields covering the hillsides beside their houses, which are grouped in rambling hamlets. The staple food is eleusine, eked out by peas, beans, corn and wild greens. They also keep cows, goats and sheep, but the cows are not surrounded by an aura of sanctity, nor are the traditional taboos of their pastoral neighbours observed. Herding does not set the *tempo* of life. Industrially they have knowledge of all the techniques practised among the serfs of their neighbours, including iron smelting, but some pursuits are the work of specialists. The important social group is the household. Ownership is essentially individualistic. Clothing and ornaments, utensils, furniture, animals, food and land—to all these individuals, particularly adult male family heads, have exclusive claims. This claim is acquired through manufacture, gift, certain forms of seizure, purchase or inheritance, and the owner may dispose of his property in many different ways. The word *nyina*, used to designate ownership, has an important extension in reference to a compound, where it includes command over the persons of the household. In his economic transactions, the master of a household need submit to no higher authority than his own. He may lend, give away, sell or destroy any of his possessions. The one kind of control which does not occur among the Ciga is testamentary. A man cannot legislate about the disposal of his possessions after his death. The individual character of property is sharply brought out by the marriage arrangements, the father alone receives the bride price. The individual kraal head is also his own master with regard to agricultural land. When once a man has acquired title by marking off its boundaries with a hoe, it remains his indefinitely and passes to his heirs. Except indirectly, women cannot own property.

Jew's Harps from Hainan Island

A GAP in the study of the distribution of the jew's harp is filled by Mr Chungshee H Liu in an account of three such instruments recently discovered in the course of anthropological investigations among the Li people of Hainan Island (*K'o Hsüch* [*Science*], 22, 1–2; 1938, Shanghai. In Chinese with English abstract). The existence of the jew's harp has been traced by many investigators among various tribes in south and east Asia and in the islands of the Pacific. Chinese scholars of ancient and modern times have recorded its use by the tribesmen along the south-western borderland of China. The original home of the instrument is said to be southern Asia, somewhere along the border-line between Burma and Yunnan. It has a wide distribution in India, Nepal, Tibet, Assam, Burma, Siam, Indo China, Malaya, Formosa, Japan (Hokkaido), and from Borneo to the Philippines, Fiji and Samoa. Of the three examples discovered in Hainan in 1934, two are of bamboo and one is of brass. Although small in size, they have a pleasing tone. Judged by their structure, they are genealogically related to those harps which are used by the Lissu of Yunnan, the Chin of Burma, the Naga of Assam and the Fan of Formosa, as well as allied with those of the Chiang of Chinghai or the Lolo of Szechuan. The discovery of the jew's harp as a cultural trait among the Li people of an Indonesian culture area fills, therefore, a lacuna in its geographical distribution and provides evidence long desiderated by students of ethnology.

Leaf Extension in *Cladium*

MISS VERONA M. CONWAY has carried out extensive observations on the rate of extension of the inner leaves of the shoot of *Cladium Mariscus*, in Wicken Fen and under various experimental conditions (*New Phyt*, 37, 3, June 28, 1938). Dr Godwin had noted the great uniformity with which these leaves extend so that if they are all cut off close to the ground, months later, after considerable extension, their cut ends will all be found within a millimetre distance of one another in length. Very suitable material is thus provided for observations upon the effect of various conditions upon leaf growth and thus conclusions may be drawn as to the habitat conditions that are optimal for the species. Miss Conway's observations have led her to the conclusion that the extension rate is closely correlated with temperature and therefore shows a strong seasonal periodicity. It is also inhibited by strong light and therefore takes place mainly at night, the rate does not vary greatly in the course of any one night, when its magnitude seems largely determined by the temperatures of the preceding day. If the plant is growing in soil which is not saturated with water, it shows a lower extension rate, and Miss Conway concludes that optimal conditions for the growth of *Cladium* include a completely water logged soil.

Economic Aspects of Potato Viruses

Two papers which lead towards a fuller understanding of the economic production of potato stocks free from virus diseases have recently been published. J. B. Loughnane and Paul A. Murphy show (*Sci Proc Roy Dub Soc*, 22, 1, May 1938) that two potato viruses, namely *X* and *F* (*Solanum* viruses 1 and 8 respectively) are transmitted from plant to plant by contact of the foliage. This happened in the still air of an insect free greenhouse, but was accentuated when the foliage was agitated by wind. Miss Phyllis Clinch, J. B. Loughnane and Paul A. Murphy further demonstrate (*Sci Proc. Roy Dub Soc* 22, 2, June, 1938) that *Solanum* virus 1 spreads considerably under field conditions, even in stocks of potatoes selected for their freedom from virus diseases. The combined results are important, for anyone who has been concerned with the production of clean stocks of potatoes can relate annoying occurrences of virus *X* It is now clear that greater attention must be paid to the initial elimination of this disease from nursery stocks, whilst a further practice of wide planting to avoid contact of the foliage, at least in the early stages of isolation should also minimize still further any chance of infection

The Hypocreales

LITERATURE upon the classification of the Ascomycetes and particularly the Pyrenomycetae, is comparatively unavailable to the general student of mycology There is in fact no collected account of later date than Cooke s Handbook of British Fungi , published in 1871 A critical study of the Hypocreales, a section of the Pyrenomycetae, by T Petch, is therefore most welcome (British Hypocreales ', *Trans Brit Mycol Soc* 21 Pts 3 and 4 243 , June 1938) The family Hypocreales includes several fungi of extensive pathogenicity notably *Dialonectria galligena* the cause of apple canker and *Claviceps purpurea*, or ergot of rye Citation of the genera *Nectria, Epichloë, Melanospora Claviceps* and *Cordyceps* should commend the importance of this family even to the amateur mycologist whilst the specialist finds a highly critical monograph of the forty one modern genera now comprised in the Hypocreales Mr Petch has described two new species in the course of his investigations namely *Calonectria tessellata* and *Gliocladium strictum* Thirty nine text figures illuminate general structure and spore form

Bacterial Rotting of Begonias

Messrs W J Dowson, W C Moore and L Ogilvie have recently described (*J Roy Hort Soc* 63 6 , June 1938) a bacterial disease of begonias, which appears to be already distributed somewhat widely in England Leaves are at first spotted with glassy areas, and later turn brown whilst the rot spreads to the petioles and stems, causing death of the plant The pathogen is a yellow bacterium which is provisionally diagnosed as *Pseudomonas begoniae* and its disease producing effect has been established by isolation and re inoculation Control lies in the destruction of infected plants followed by such garden hygiene as the propagation of disease free cuttings in sterilized soil

The Fluorine Molecule

THE internuclear distance in the fluorine molecule has been calculated as 1 45 A by L O Brockway (*J Amer Chem Soc* , 60, 1348 , 1938) from electron diffraction measurements in the gas Half this value is 0 73 A , whereas the covalent radius for the fluorine atom obtained by extrapolation of the carbon, nitrogen and oxygen radii and also obtained from the observed distance in methyl fluoride is 0 64 A , so that the distance in the fluorine molecule is about 14 per cent greater than the value expected for a normal covalent single bond The author points out that the accuracy attained was, on account of experimental difficulties, less than that of other electron diffraction determinations, but considers that the result is not in error by more than about 0 05 A

Hydration and Denaturation of Proteins

ON the cyclol theory, proteins have cage like molecules Water can be associated with these molecules in three ways first, by direct co ordination with the fabric, secondly, inside the hollow shell of the molecule, thirdly, in the protein crystal, in the inter molecular spaces within the crystal cell (D M Wrinch, *Phil Mag* 25, 705 , 1938) It seems likely from the open lattice structure of the protein molecule, that many protein crystals will contain not only water molecules but also foreign ions The crystallizability of the native proteins indicates that their molecules must have a more or less rigid structure All the amino acid residues of the native protein are present in the denatured protein yet the latter has never been obtained crystalline Wu concludes that there must be some linking of the residues in the native protein which has been loosened in the denatured protein allowing the molecule to become flexible Northrop points out the entropy of native protein is very much less than that of denatured protein suggesting that the former has a fixed configuration and the latter a number of possible configurations The cyclol cage has regions of greater and lesser stability and any factor increasing the instability of a particular region could lead to a tearing open of the cage molecule The migration of protein molecules to an aqueous surface could form such a factor since the passing of the hydrophobic R groups out of the water at the surface would lead to a general disturbance of the water relations of the protein molecule Protein molecules are denatured when they form films and lose water of hydration The thickness of the film may be as small as the thickness of a single amino acid residue, suggesting a complete tearing open of the cage like molecule On the other hand, it may be greater suggesting partial opening or the folding over of a flat fabric

New Application of Photo-electric Cells

THE practical applications of photo electric cells are continually expanding According to a report issued by Science Service of Washington, D C , C W La Pierre and A P Mansfield, of the General Electric Company of America, have described a machine to the American Institute of Electrical Engineers which determines the skew of the cloth and controls the apparatus which straightens it When cloth leaves the loom, warp and weft—the lengthwise and crosswise threads—are perpendicular to each other, but after the cloth has been bleached, washed, starched and dried the weft may be appreciably out of position This skew is important, because any designs printed on the cloth will be distorted after the cloth is cut into small pieces The cloth is straightened by passing it through a device called a 'tenter , which contains fingers for gripping the edge of the cloth and stretching it while still wet so as to eliminate the skew Formerly the controls were hand operated, the operator gauging the amount of stretch by the simple expedient of watching the cloth carefully , but this procedure is subject to human limitations and is only satisfactory for relatively coarse weaves and low cloth speeds The authors state that by means of their electrical device the work can be done much faster and more accurately

Carbohydrates of Well-Defined Molecular Weight in Plant Juices

By Prof. The Svedberg and Nils Gralen, Institute of Physical Chemistry, University of Uppsala

THE attempt to bring the solid carbohydrates of plants and animals, for example, cellulose, starch, glycogen and their derivatives into solution has so far resulted in polydisperse systems not possessing well defined molecular weights[1] This fact may be taken as an indication that the question is wrongly put, that such structures as cellulose and starch do not spontaneously form particles of definite mass (molecules) and therefore cannot be broken down to real molecular dispersion without profound chemical change

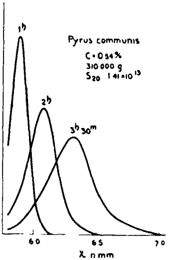

Fig 1

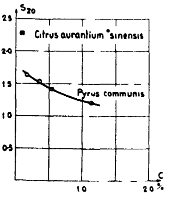

Fig 2

In another class of high molecular compounds, the proteins, we meet with a similar phenomenon Keratin, fibroin, myosin and other proteins which occur in a semi-solid state do not as a rule give solutions of well-defined molecular weight On the other hand, all the proteins of the body liquids are characterized by their well defined molecular weights.

From these statements it would seem reasonable to conclude by analogy that there is a fair possibility of finding carbohydrates of well defined molecular weight in plant juices This would mean that when Nature produces a substance which occurs as a solute in a natural liquid, this substance may form well defined molecules We do not know much about the final stages in the building up of cellulose and starch It is generally believed that the synthesis takes place from the simple sugars through intermediate compounds similar to those observed in the enzymatic breakdown processes studied *in vitro*, but nothing definite is known with regard to those hypothetical stages It is possible that these substances exist in solution in plants as high molecular carbohydrates of well defined molecular weight From this point of view, an examination of plant juices with appropriate modern methods such as ultracentrifugal sedimentation, diffusion and electrophoresis should be of considerable interest

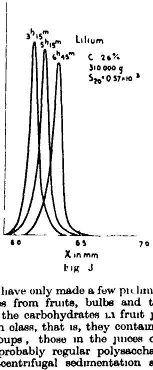

Fig 3

So far we have only made a few preliminary studies of the juices from fruits, bulbs and tubers The majority of the carbohydrates in fruit juices belong to the pectin class, that is, they contain methylated carboxyl groups, those in the juices of bulbs and tubers are probably regular polysaccharides

The ultracentrifugal sedimentation and the diffusion of pectin from apples, pears, plums and oranges was determined directly in the juice and on material precipitated with alcohol These substances are not monodisperse but better defined than starch or cellulose solutions The pectins from apples, pears and plums have approximately the same molecular weight (25,000–35,000), while that from oranges is definitely higher (40,000–50,000) As an example, the sedimentation and the relation between sedimentation constant and concentration for the pectin in pear juice is shown in Fig 1 and 2 A value for the sedimentation constant of orange pectin is also inserted in Fig 2 The increase of sedimentation with decreasing concentration indicates interaction of the molecules due to dissymmetrical shape or hydration

The carbohydrates in the juice of bulbs and tubers have proved more nearly monodisperse in sedimentation and diffusion Fig 3 shows the sedimentation of the carbohydrate from a *Lilium* bulb The molecular weight was 16 000

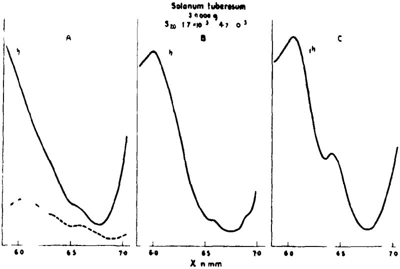

Fig 4

There is a noticeable change in the sedimentation picture with the development of the plant When a bulb or a tuber begins to sprout high molecular carbohydrates appear in the juice in higher concentration than before As a rule, two well defined components can be distinguished This may be taken as an indication that the breaking down of the reserve carbohydrate (starch or inulin) passes through two steps before the low molecular stage is reached As examples, in Fig 4 the sedimentation diagram from the juice of a dormant potato tuber (*A*), from one just beginning to sprout (*B*) and from one in the midst of sprouting (*C*) is given With increased activity the two high molecular components become more and more noticeable The dotted curve in (*A*) represents the sedimentation of the juice after removing the low molecular material by dialysis This shows that the two maxima are present even in the juice of the dormant tuber although in very low concentration Similar curves have been obtained with the juice from the tubers of *Helianthus tuberosus* and *Ranunculus ficaria*, and from hyacinth bulbs

By ultracentrifugal analysis we have also found traces of obviously monodisperse high molecular compounds probably carbohydrates in the juice from hyacinth leaves and in the sap from birch trees

It is hoped that investigations along these lines will help to throw some light on the processes of carbohydrate metabolism in growing plants

Physical Chemistry of Surfaces

Annual Meeting of the Bunsen-Gesellschaft

THE forty first annual assembly of the Bunsen Gesellschaft was held in Breslau on June 2 3 the principal theme of discussion being The Physical Chemistry of Surfaces The symposia of the Bunsen Gesellschaft are organized somewhat differently from those of its younger sister the Faraday Society All papers are delivered in full, only abstracts being available beforehand Papers delivered fall under three heads (*a*) summary reports invited from various experts, intended between them to cover the whole field of discussion (*b*) shorter contributions bearing on the main theme, (*c*) miscellaneous physico chemical contributions (*b*) and (*c*) were delivered in parallel sittings This produced a very full two day programme with little time for discussion—in fact there was no time whatever for public discussion on section (*a*) This disadvantage is appreciated, and the society has recently adopted a policy of holding smaller extra *Tagungen*, more after the model of the Faraday Society, in which discussion can be a principal feature

Prof P A Thiessen made some general introductory remarks and took the chair R Brill discussed surface films on water, a method of investigation which has been somewhat neglected in Germany since the time when Fraulein Pockels its originator had to arouse Rayleigh s interest to secure publication of her work He discussed in great detail the two dimensional equation of state and finally the work of Blodgett and Langmuir on built up multilayers Of all recent developments mentioned in the symposium, the latter undoubtedly shows the most promise of great expansion and exciting progress In a single lecture of such detail it was naturally impossible to deal with everything, but it is unfortunate that such well established novelties as measurement of film potentials and the investigation of chemical reactions in monolayers were never brought before the meeting

An interesting paper by K Neumann concerned molecular motion in surfaces He dealt first with the streaming set up at liquid surfaces by capillary forces, which often plays a large part in the rapid dissolution of surface active substances, and, secondly, with surface diffusion on solids—a field of research first opened up by the work of Volmer and Estermann on the growth of mercury crystals Both experiment and simple theoretical considerations show that the activation energy for change of position of a molecule on a crystal surface is roughly one fifth of the heat of evaporation, whence it follows that a molecule after condensation will usually change its place some thousands of times before evaporating again. This enables the regular growth of crystals, which is otherwise difficult to reconcile with the existence of condensation coefficients of the order of magnitude 1. The activation energy for the motion of single ions on the surface of an ionic crystal is not much less than the heat of evaporation, but adsorbed pairs of oppositely charged ions can readily move around one another. This accounts for the surface diffusion of sodium chloride, for which experimental evidence was presented.

O. Hahn reported on the investigation of surface processes by radioactive methods. Of particular interest is his 'emanation method' of investigating the 'inner surface' of a solid. This is a development from the older adsorption method used by Paneth. Hahn makes solid preparations containing minute quantities of radium, and determines the nature of the surface by the readiness with which the material gives up emanation. By this means, changes in the surface of a material (for example, iron oxide hydroxide gel or a catalytic thorium oxide) with time or heating can be followed with great sensitiveness. Later in the meeting, K. E. Zimens reported on theoretical work of S. Flugge which shows that the method can also be used to investigate diffusion constants in solids, in principle quite easily for values as small as 10^{-25} cm ^{2}/day. (The smallest *measured* diffusion constant in a solid is 10^{-17} found by Cremer in solid hydrogen from the rate of disappearance of isolated *ortho* hydrogen molecules, which are only destroyed by magnetic reaction with one another.) A very remarkable result obtained by the older methods is that found by K. Starke, that mixtures of $ZnO-Fe_2O_3$ or $ZnO-Cr_2O_3$ in equimolecular (spinel) proportions develop a very much increased adsorptive power for lead above that of the components, even at room temperature.

Th. Schoon dealt with electron diffraction as a means of investigating surfaces. He discussed the evidence for the Lennard-Jones effect (predicted contraction of the surface layers of ionic crystals, and a corresponding expansion in molecular crystals), which remains doubtful, owing to uncertainties about the refractive index for electrons of the possible presence of adsorbed gas layers. Among other points dealt with were the depth of penetration of electrons, by which is meant the depth to which an electron at grazing incidence (3°) can pass in and out of the crystal, being scattered only once. From the fact that with 25 kv., cetyl palmitate and stearic acid crystals, grown from hydrocarbon solvents, give the same diagram, but differ at 40 kv., it is concluded that electrons at these voltages have respectively shallower and deeper penetrations than 20 A.

P. Harteck dealt with the various types of adsorption (Van der Waals adsorption, capillary condensation, and reversible and irreversible activated adsorption). R. Suhrmann reported on electron emission phenomena. C. Wagner gave a masterly survey of reactions at phase boundaries, classified according to the nature of the velocity determining stage. This was so closely packed as to be incompressible, and it is recommended that the original paper be referred to when it appears in the *Zeitschrift für Elektrochemie*. K. Fishbeck made much the same attempt with narrower limitations. Finally, G. M. Schwab surveyed surface catalysis. This paper also, unfortunately, lends itself to compression as little as the subject lent itself to compression into a single lecture of 35 minutes.

An arbitrary selection must suffice for the miscellaneous papers. L. Bergmann demonstrated a number of interesting experiments with supersonics. Th. Förster showed how it is that the strength of a C–H bond is influenced by the state of binding of the carbon (single, double or triple bond, or strained ring). The mutual influence arises from the fact that the sum of the mixture ratios of *2s* and *2p* states in the four bonds must remain constant and equal to 1 : 3. Reduction of the angle below the tetrahedral angle reduces the ratio below 1 : 3, and hence increases it in the other bonds. The maximum binding is reached with a ratio of about 1 : 1 (C–H bond in acetylene). With nitrogen, the bonding of which is not a mixture of electron states, but purely *2p* in the first approximation, there is no mutual influence, as the Raman spectra have shown. Schmid and Larsen showed that the increase of conductivity at high frequencies (λ 12 m. and 20 m.) is very large in solutions of soaps, etc., containing ionic micelles. This indicates that the reduced conductivity and activity in such solutions is a Debye-Huckel electrostatic effect (theory of Hartley and others) rather than reduced dissociation as supposed by McBain. H. J. Antweiler and M. v. Stackelberg reported further experiments on the peculiar currents of liquid with speeds up to 8 cm./sec. which are set up in the electrolyte at liquid metal cathode surfaces under certain conditions. This can now be satisfactorily interpreted as a cataphoretic effect. K. Clusius and K. Weigand have measured the pressure dependence in the transformation II (isotropic) ⇄ III (anisotropic), in solid hydrogen sulphide and heavy hydrogen sulphide. The hysteresis in this change is still something of a mystery, but the authors suppose it means that many molecules must become rearranged simultaneously. X-rays indicate that the *S* atoms scarcely move in the transition. F. C. Frank presented a descriptive theory of the phase change liquid to liquid crystal, showing the way in which the quasi-crystalline structure of the former can develop semi-continuously into the latter. This was intended to be a contribution to the general theory of phase changes from the point of view that this is one of the simplest of all crystal–non-crystal transitions.

On the whole, in spite of the high quality of individual contributions, the meeting produced nothing of great novelty. This applies particularly to the main theme. Partly this reflects a certain lack of enterprise in German physical chemistry, which is at the moment mainly distinguished by painstaking covering of well-trodden ground; partly it indicates that the time was well chosen for a summarizing symposium designed to report progress, rather than to make it.

There were as usual a number of social events in a programme which scarcely left a minute unprovided for. Of these the most memorable was a concert in the *Schloss*, with music by Mozart and Frederick the Great—the latter appropriately as the one who gave the *Schloss* its present inner form. At the final dinner, we learnt that this was the fortieth *Bunsentagung* which Prof. Bodenstein had attended, without interruption. Finally, many members took part in a visit to the Waldenburger Bergland and Salzbrunn, and some continued home *via* the ridge way of the Riesengebirge.

F. C. FRANK.

Guy's Hospital Medical School

New Institute of Pathology

THE new Pathology Building at Guy's Hospital Medical School, which was opened on June 23 by the Chancellor of the University, the Earl of Athlone, completes the rehousing of the School and Hospital laboratory departments. It makes a valuable addition to the facilities available for carrying on medical research in London by providing suitable modern accommodation in close association with one of the largest hospitals.

In welcoming the Chancellor, the Dean of the Medical School pointed out that a comparatively small number of hospitals, such as Guy's Hospital, which had originally been founded for the care and cure of a small neighbouring population, had developed into the training ground for the medical services of the nation. To-day, however, the solvency of these hospitals is in imminent danger, and the whole clinical training of the medical student is not only handicapped but is also seriously threatened by the desperate financial straits in which these essential hospitals find themselves. "It is one of the queerest anomalies," he said, "of this British civilization that the training for the most important and most devoted of its public services should be hampered at every stage by being committed to an existence of perpetual mendicancy."

The Chancellor, in replying, stated that the University viewed with great satisfaction every effort made by its constituent schools to provide themselves with accommodation and equipment worthy of institutions of university status, and he congratulated the Medical School of Guy's Hospital on the fulfilment of its wise policy of concentrating all the departments of the School on one site. He also said that the University recognizes with appreciation that the present building has been largely paid for out of the ordinary funds of the School, without public appeal, though with some financial assistance from the Court of the University. "The reputation of the hospital," he said, "depends on its school, and the reputation of the school depends on the financial stability and efficiency of the hospital."

The opening of a large modern medical school building designed to afford extensive accommodation for research, provides an opportunity of directing general attention to the seriousness of the position in which those responsible for medical education in this country are now finding themselves placed. The prescribed course of education for a medical qualification is at present divided into two parts of roughly equal length. In London the earlier half is carried out in well equipped departments, like that now opened at Guy's Hospital, belonging to institutions which are carefully controlled and inspected by the University authorities and liberally supported by University funds. The provisions for teaching in the second half, however, present a striking contrast with those in the first. They depend almost entirely upon materials and facilities provided by more or less independent institutions—the teaching voluntary hospitals—many of which are very much older than the University itself. For some years these essential hospitals have been in straitened circumstances, and the teachers of clinical subjects in their wards and out-patient departments have been faced with increasing handicaps upon their activities. Though these obstacles have been greatly lessened by the loyal support given by the teaching staffs, as well as by the ingenuity of the administration in making resources stretch as far as they will go, it should now be generally realized that medical students are no longer receiving the best training which the medical advances of the past fifty years have made possible. Nor is there any assurance that even the present hospital facilities will be continued in the future on the same level as in the past. In their endeavour to maintain their former predominant position many of the voluntary hospitals, in recent years, have seriously overstrained their resources, and are adding yearly to accumulating deficits. They are faced, therefore, with the very serious alternatives of either curtailing the facilities they place at the disposal of the University for medical education or of extending in some direction the basis of their financial support. What direction such extension should take will require careful consideration, especially in view of the double duty that these institutions undertake: they provide hospital beds for the population of London on the one hand and medical practitioners for the country as a whole on the other. To meet these two distinct claims it would seem that both local and national support must be forthcoming.

University Events

Belfast.—Arrangements have been made for co-operation between the University and Armagh Observatory, and Dr. E. M. Lindsay, astronomer at Armagh, has been appointed part-time lecturer in astronomy in the University. Dr. Lindsay will continue to hold his post of astronomer at Armagh.

Mr. O. G. Edholm has been appointed to the newly created lectureship in physiology. Mr. Edholm is at present assistant lecturer in physiology at King's College, London.

Cambridge.—The electors to the John Humphrey Plummer professorship of mathematical physics have elected Prof. R. H. Fowler, fellow of Trinity College, from October 1. Prof. Fowler resigned from the chair on his acceptance of the directorship of the National Physical Laboratory on the resignation of Prof. W. L. Bragg (see NATURE, June 4, p. 1002); but has been advised to withdraw his acceptance of this post for reasons of health, and signified willingness to be re-elected as professor of mathematical physics.

D. J. Bauer, of Trinity College, has been re-elected to the Michael Foster studentship in physiology for 1938–39. Mr. Bauer, who was educated at King's College School, Wimbledon, graduated with a first class in both parts of the Natural Sciences Tripos. The annual value of the studentship is £105.

Oxford.—In Convocation on July 30 the honorary degree of D.Sc. was conferred on Prof. C. G. Jung, professor of psychology in the University of Zürich and president of the Tenth International Medical Congress for Psychotherapy meeting in Oxford.

Southampton.—Dr. P. Ford, lecturer in charge of the Department of Economics, has been elected to the chair of economics and head of the Department of Economics and Geography in University College, Southampton.

Miss F. C. Miller has been appointed senior lecturer in geography.

Science News a Century Ago

The Horticultural Society

A MEETING of the Horticultural Society was held on August 7, 1838, H M Dyer, vice president, being in the chair "The specimens" said *The Times*, "exhibited some interesting varieties One of the most valuable was the vanilla plant, cultivated by Professor Motreu, of Liège, who gave it the same attention as is employed in the cultivation of melons and cucumbers In the first year of its growth it produced 50, and in the second year upwards of 160 fruits, and the success of its cultivation led to the belief that it might be introduced into Europe as an article of profit From the gardens of the Society was a Trinidad pineapple weighing 5 lb 12 oz This is one of those extraordinary fruits that grow on that island, near a pitch lake, and are there met with of a weight of 28 lb , which they might attain in this country, were the soil and cultivation properly known The cultivation of the vanilla plant was dealt with a week or two later by Prof Motreu in a paper to the British Association in Newcastle

The *Athenæum* and School Buildings

In its issue of August 11, 1838 the *Athenæum* dealt at length with a Report of the Secretary of the Board of Education on the Subject of School Houses published at Boston, U S A Always a persistent advocate of national education, the *Athenæum* remarked that, ' Habituated as we are to opposition to all national education that is directed to a higher object than a polemic triumph, we were almost startled at the plain good sense of the men of Boston, who have brought their time and attention to bear upon the philosophy of school accommodation Planning, ventilation, windows, lighting, heating, location, desks and seats, and play grounds were all the subject of discussion in the report, which said that ' when it is considered that more than five sixths of all the children in the State spend a considerable portion of the most impressionable period of their lives in the school house, the general condition of those buildings, and their influence upon the young stand forth at once as topics of prominence and magnitude All those readers who had the improvement of our domestic education at heart were enjoined to procure reprints of the report for cheap or gratuitous circulation

Honours to Men of Science

UNDER the above heading, the *Mechanics Magazine* of August 11, 1838, said ' Sir John Herschel is, we believe, the first Englishman who has ever received a baronetcy purely on account of his scientific acquirements His father was only a Hanoverian knight, which was also the honour enjoyed by himself previous to the late coronation Sir Edward Lytton Bulwer is only the second *literary* baronet, having been preceded by Sir Walter Scott No great inventor has ever received a similar honour , Sir Richard Arkwright was indeed knighted, but that was not on account of his mechanical merits, but in the usual routine, as the bearer of an address of congratulation on His Majesty s escape from the knife of Peg Nicholson, or some equally important occasion " In connexion with this, it may be remarked that Lord Liverpool, when Prime Minister, offered a baronetcy to Watt, who, however, declined it,

REPORT OF THE RADIUM COMMITTEE FOR 1937

10 110 millicuries of radon were issued during the year and reports received from hospitals and the larger private users record the treatment of 502 cases of malignant and 97 of non malignant diseases Of all cases of malignant disease treated by any method in these institutions, more than fifty per cent received radium treatment Out of a large number of malignant cases of which detailed results are recorded, some sixty per cent were apparently cured, or at least were free from symptoms at the end of a year Records are also included showing the number of cases treated in former years which are known to be still alive One large user comments on the imperative need for taking all possible steps to ensure that patients come forward for treatment before the disease has advanced so far as to render the results hopeless

W R G ATKINS A modified use of the hæmocytometer for counting sparse fields By suitable focusing, it is possible to arrange that the entire circular microscope field just encloses the square millimetre of the hæmocytometer, and thus the entire field being of a known area can be used for counting purposes In this way a number of sample counts can be effected on a single slide

Inland Water Problems

IT is inevitable that in a country of the population and extent of the United States of America, the administration of the various public services should be framed on a scale of greater magnitude and amplitude than is practicable or desirable in smaller countries. Yet even if this be admitted, there is no reason why in any two countries, kindred objects of public concern should not be pursued with equal intensity of effort and corresponding breadth of outlook Where a service is essential for the general welfare, an equivalent degree of enterprise and energy may not unreasonably be expected in both cases

This reflection presents itself in considering a comparison of the respective attitudes of the British and American Governments in regard to the question of the national administration of water, one of the most essential services of a civilized community Until recently, in Great Britain there had been no attempt at the effective co-ordination of water resources of the country on a national and systematic basis, and little control over their exploitation beyond the slight and general supervision of Parliament over Bills relating to powers for local supplies. It was left in rather a vague, haphazard way to the Ministry of Health to take action, if and when necessary, with the result that matters in general were allowed to shape their own course, the Ministry only dealing with specific problems as they arose, a characteristically British method, commonly known as 'muddling through'. As for any definite public statement or programme of policy to be adopted for the most efficient and beneficial use of water supplies in regard to the nation as a whole, serious consideration was rarely given to such matters in official or political circles Indeed, until forced into action by the pressure brought to bear upon Parliament in consequence of the drought of the years 1933 and 1934, and the joint representation of the British Association and the Institution of Civil Engineers, no attempt at a systematic investigation of the water resources of Great Britain was ever contemplated Only with some degree of ministerial reluctance, after an unsuccessful attempt to describe it as superfluous and unnecessary, was an Inland Water Survey Committee instituted in 1935 under the Ministry of Health Since then, there has been appointed, also under the Ministry of Health, a Central Advisory Water Committee, which has been engaged in reviewing the work of nine independent Regional Advisory Committees in various parts of the country. The first report of this Central Committee has just been issued, and it affords an indication of the lack of co-ordination which prevails between these bodies and external interests related to water supply.

In the United States, the subject of inland water control has exercised a far greater degree of Governmental consideration and the matter has been dealt with on broad national lines. There is, in the first place, a National Resources Committee dealing with all the national assets of the country, and an important section of this is the Water Resources Committee, including representatives of the War, Interior, and Agricultural Departments, Public Health Service and Federal Power Commission. Through the activities of this body, a co-ordinated plan and policy for each drainage basin in the country has been laid down, and the individual plans have been reviewed and co-related in respect of national needs and budgetary limitations. This has been accomplished with the aid of forty-five drainage basin committees, constituted on a democratic basis, with popular representation

It is pointed out that a unified system of water control, as opposed to a medley of unrelated projects, is essential in the best interests of the nation, and that an integrated federal policy is required in order to deal satisfactorily with various types of water problems having interdependent relationships The main principles underlying the determination of the adopted programme have been described as a "concern for the promotion of public safety, public health, public convenience and comfort and public economic welfare" so as to secure "the establishment or maintenance of a high standard of living".

Elsewhere in this issue (p 280) will be found particulars of a six-year programme which has been recommended to Congress, involving in the total an estimated expenditure of 891 million dollars, or a "weighted average" per annum of 200 million dollars—say 40 million pounds Expenditure on this huge scale indicates profound appreciation of the necessity for a far-reaching development of national resources which, in the case of America, are themselves of enormous magnitude

The water resources of Great Britain are of much more modest extent, but, none the less, they call for careful conservation and development, and the point may well be raised again, as on a previous occasion (see NATURE, August 4, 1934), whether identification of the Inland Water Survey with the restricted outlook of the Ministry of Health is in the best interests of the country Water is not the special preserve of any particular Government Department: it is a national asset We have advocated—and still believe the scheme to be best—the establishment of an entirely untrammelled investigation under the Department of Scientific and Industrial Research, the impartiality and independence of which would secure to the nation at large an unbiased outlook on this matter of national concern. The Ministry of Health has its own problems to face, and is not in any way concerned with industrial or commercial requirements, or with the needs of agriculture, fisheries and navigation. It cannot then be claimed that these interests are adequately represented as they should be in a matter of this kind.

The fact of the existence of the Central Advisory Water Committee does not invalidate our contention in the least It, too, is a purely departmental Committee and although its functions (*inter alia*) are "to advise the Government Departments on questions relating to the conservation and allocation of water supplies", yet, being under the ægis of the Ministry of Health, it cannot, in our view, have that independence of attitude and breadth of outlook which should characterize a committee of this kind It is true that it includes among its members, individuals associated with a variety of water interests, but none the less it has to supplement its sources of information with the assistance from other departments of "assessors". one from the Board of Trade, two from the Ministry of Agriculture and Fisheries, one from the Ministry of Transport and one from the Department of Scientific and Industrial Research. If the representations of these assessors are to carry their full weight, the assessors themselves should have the prestige and standing of members of the Committee The matters with which they deal are not side issues, but questions of serious importance

We have no intention of making any reflection whatever on the composition of the Inland Water Survey Committee and the Central Advisory Water Committee, or on the particular steps taken by the Ministry of Health to establish them The cause of criticism lies in the fact that the matter is of such far-reaching importance to all classes of the community that, as in the case of the United States, it calls for the existence of a comprehensive and strictly independent Water Resources Committee on which there would be direct representation of all the varied interests in inland water administration, private as well as corporate This would naturally include certain Government departments, some of which are remote from the sphere of public health, and relate to the wider aspects of national economy in regard to commerce, transport and industrial development

A national programme of development drawn up by such an impartial committee would command far greater confidence and support when submitted to Parliament than the unavoidably biased recommendations emanating from a single Ministry. Without such a programme and policy Great Britain must inevitably continue to drift in an aimless way, subject to visitations of drought and flood, and through lack of vision and forethought, reprehensibly neglecting the systematic development of one of the most important natural assets of the country.

Scholiasts and Science

Ancients and Moderns:
a Study of the Background of the "Battle of the Books" By Prof. Richard Foster Jones. (Washington University Studies, New Series Language and Literature, No 6) Pp xi + 358 (St Louis, Mo Washington University, 1936) 3 dollars

> "Then, *Aristotle*, observing *Bacon* advance with a furious Mien, drew his Bow to the Head, and let fly his Arrow, which mist the valiant *Modern* and went hizzing over his Head, but *Des Cartes* it hit, the Steel Point quickly found a *Defect* in his *Headpiece*, it pierced the Leather and Pastboard, and went in at his Right Eye The Torture of the Pain whirled the valiant *Bow man* round, till Death, like a Star of superior Influence, drew him into his own *Vortex*"

THUS Jonathan Swift, in his satire "The Battle of the Books", written in 1697 to ridicule those of his contemporaries who contended that the performances of their times exceeded those of the ancients The above passage, and one in which Harvey, Paracelsus and Galen are concerned, are about all that refer to the particular revolt against the ancients that culminated in the foundation of the Royal Society, but nevertheless Prof Jones gives the subtitle "A Study of the Background of the Battle of the Books" to his book, which is a heavily documented account of the wordy warfare that accompanied the rise of the experimental method in England It is essentially a history of polemic, and might well itself have appeared under Swift's title, but with Swift's book it has little to do The title-page may mislead the student of literature

Prof. Jones is a whole-hearted champion and admirer of Francis Bacon, and attributes the triumph of the experimental philosophy to him alone—"the achievement of this desideratum was the destiny of one man—Sir Francis Bacon" This, and a contention that the Puritans did much to make Bacon's work popular, in connexion with schemes for educational reform, especially the putting down of the teaching of divinity, are his constant theme, in support of which he adduces a large number of authors of various degrees of distinction, or of obscurity, Hakewill, Hartlib, Durie, Starkey, Webster and the like.

Prof. Jones certainly succeeds in proving that between 1640 and 1660 Bacon was often cited as a champion by such men, in their writings against the abuse of classical authority and in favour of educational reform and the utilitarian cultivation of the sciences None of these men, however, cuts much of a figure as a practical experimenter, or, indeed, as an original investigator of any kind Prof Jones is, accordingly, often driven to the type of unsupported assumption that characterizes so many of Francis Bacon's most ardent supporters He tells us, on the strength of the fact that Wilkins refers to him once or twice, that "Bacon was certainly the chief source of Wilkins' ideas", although Wilkins, in the book in question, set out to expound and defend the Copernican theory, which Bacon ridiculed Wilkins further adduces Galileo and Kepler, whom Bacon was so far from appreciating that he never refers to either of them Prof Jones tells us that "one who has been plausibly identified as Robert Hooke" published a continuation of Bacon's "New Atlantis" he adduces no support of this identification, except that the book is by R H Esquire It is most improbable that it was by Hooke It was published in 1660, and Aubrey, who was Hooke's great friend, and stayed with him in his lodgings so frequently, tells us that the first thing he published was the known "An Attempt for the Explication of the Phenomena observable in an Experiment published by the Hon R Boyle .", a little tract which came out under his full name in 1660. Hooke was at the time Robert Boyle's assistant, busily engaged in his beloved experimenting, and it seems unlikely in the highest degree that he should have had the inclination or leisure to publish such a book in the same year, that he should use his initials after having already used his full name, and that he should call himself Esquire—which he was not In any case, it seems to some of us that the book is completely out of Hooke's character

As an example of how far Prof Jones will go, he says, "Though he does not mention Bacon, Worcester is an outstanding example of the hold which the inventive spirit, fostered by Verulam, was fixing on men". There is nothing to show that Bacon had any influence whatever on Worcester—catalogues of inventions, usually illustrated and supplied with detail, were current long before Bacon's influence can possibly have been felt, for example, Ramelli and Zonca, of which traces are to be found in Worcester's booklet—while anyone who has read Worcester's "Century of Inventions" will be hard put to it to find any trace of real inventive achievement in this mere catalogue of projects and devices, many of them clearly impossible and others as clearly never tried, let alone perfected as the author claims for all of them One example may suffice How to make an artificial bird to fly which way and as long as one pleases by or against wind sometimes chirping other times hovering still tending the way it is designed for No directions are given as to how any of the inventions are to be constructed The contention that Worcester invented a practicable steam engine is scarcely taken seriously to day (see *Trans Newcomen Soc* 13 75)

There is one man of science who frequently cites Bacon in terms of warm admiration namely Robert Boyle but even here Prof Jones gives way to exaggeration After quoting a large number of citations of Bacon by Boyle he says the above are not a tithe of the citations which might be produced I shall be astonished if Prof Jones can make this good—at any rate the folio edition of Boyle s work 1772 has a very good index and Prof Jones has cited nearly all the references to Bacon to be there found Putting aside this hyperbole however there is no doubt of Boyle s veneration for Bacon and a further proof of the respect in which Bacon was held is that his picture appears in the Hollar frontispiece to Sprat s History as *Artium Instaurator* Prof Jones finds this natural but then he nowhere considers seriously Bacon s actual achievement or in particular the criticisms of Lasson and Duhring or of Liebig Draper and Sir Oliver Lodge men of science who have carefully considered Bacon s writings

In spite of his boast that he brought a new method and of his attacks on Aristotle Bacon s outlook and terminology were Aristotelian rather than modern The experimental method which he described namely the gathering of vast bodies of observations by journeymen which were then to be mechanically raked over by a philosophical machine (cf Prof Jones s remark This democratic spirit is further revealed in his elaboration of Bacon s idea that the [scientific] method requires of its devotees neither learning nor genius) was incapable of being turned to any practicable use and further he not only had no conception of purposeful experiment or of the working hypothesis but definitely failed to recognize the scientific work of prime importance that was going on around him He was a contemporary of Kepler Galileo Gilbert and Harvey—Harvey was in fact at one time his physitian according to Aubrey —but he has nothing to say of their work except for a casual condemnation of Gilbert Harvey s derisive he writes philosophy like a Lord Chancellor was justified

What then is the reason that Bacon was so constantly cited by the enlightened amateurs who fought for the experimental method but except for Boyle scarcely at all by the great pioneers who founded modern science Perhaps it is to be sought in the fact that Bacon with his great position furnished that authority for their arguments which was needed by those who had cut themselves loose from Aristotle s authority A man of Bacon s high office and high reputation was a most valuable symbol of the importance the respectability of the new experimental learning He advocated the study of Nature the devotion of funds to experimental learning and the building of a great foundation for experimental investigation Those who were working for these things could cite his great name as patron and protector so that for the controversialists he was a man of the greatest significance The methods which he advocated however and his whole outlook on experimental research which was purely utilitarian constituted a retrograde movement rather than an advance and confronted with the fact that Galileo and Gilbert had founded modern science and that Kepler had revolutionized astronomy before Bacon s works were known it is hard to argue that Newton Huygens and their great contemporaries would have been one whit the worse or the advance of science one moment retarded if Bacon had never lived For the history of education and opinion Bacon is of great significance on the history of science as such he exercised we believe no influence Prof Jones makes no distinction

Prof Jones s book is deserving of high praise in that it contains a large amount of valuable material not hitherto brought together especially that bearing on the hundred years before 1650 He points out that there was a widespread belief during that period that the world was actually in decay that learning was in its dotage and that the ancients had laid down limits beyond which we could not hope to progress and he quotes from various lesser known authors passages that clearly express that point of view and describes the campaign which was conducted against it He also gives a good account of the controversy that attended the birth of the Royal Society laying stress on the writings of Casaubon the most enlightened of the defenders of antiquity and duly describing the writings of Sprat and Glanvill Of the position of Stubbe who carried on so sustained and senseless an attack on Glanvill he does not however give a correct picture Stubbe s almost insane hatred of the Royal Society his fanatical spirit and his intemperate charges seem to puzzle the author It has been shown by Dr Harcourt Brown that Stubbe was merely a hired pamphleteer a Man of as much Acrimony as Wit who drew his pen with great virulence and layd about him most furiously indeed and was well gratified by Dr Hamey for it Dr Hamey being an important figure in the College of Physicians, a body said to have been jealous of the new Society. "It is probable," says Harcourt Brown, "that we do not know more than a very small share of the real motives which involved the Royal Society in such a storm of criticism" the Stubbe incident is one that he happens to have cleared up

The book is clearly the fruit of long study, and is heavily documented concerning authors of whom little is elsewhere available It is all the more unfortunate that reference to its riches is made so difficult Not only is there no index, but also the management of the notes, of which there are some seventy pages at the end of the book, is not a convenient one Sometimes the title of a book is quoted in the text and reference has to be made to the notes for the author. sometimes the author's name is quoted, and reference has to be made for the book The numbering of the notes begins afresh for each chapter, so that unless the reader happens to remember the chapter which he is reading, he has to turn back to find it, before he can look up his note The present reader, at any rate, has found the system very troublesome He realizes the value of the book, but also realizes that if, in six months' time, he wants to find any particular passage about some remembered name, he may have to search the whole of the book to find it again A small fraction of the time that must have been spent in gathering the material would have sufficed to digest and order it in such a way as to double its value to the student

E N DA C A.

Migration of Man: Past, Present and Future

Environment, Race and Migration: Fundamentals of Human Distribution, with Special Sections on Racial Classification and Settlement in Canada and Australia By Dr Griffith Taylor Pp xv + 483 (Toronto University of Toronto Press, 1937 3 50 dollars London Oxford University Press 15s net)

EVER since the historic controversies of Darwin's days, the evolution of man has been at once the subject of popular appeal and, scientifically, a problem of peculiar difficulty The layman indulges his fancy in speculating about 'the missing link' and the 'cradle of the race', the anthropologist often becomes increasingly reticent the more he knows. Which means that anthropology is perhaps still in its 'formative' stage, and knowledge of man, both of prehistoric times and of the present day, is not yet sufficiently advanced for very definite conclusions as to the exact location of the earliest centres of human evolution or the mechanism of the distribution of races

Prof. Griffith Taylor holds a theory (which he has advocated for a number of years) that there was one 'cradle' of evolution, namely, in Central Asia, and thence spread successive waves of racial stocks—Neanderthal, Negrito, Negroid, Australoid, Mediterranean, Nordic and Alpine In Parts 1 and 2 of the present work, he elaborates this theory and attempts to survey at once the characteristics and distribution of the different races, the migration routes of primitive man, the climatic and geographic factors at the present day as well as the fluctuations in both these attendant upon Pleistocene glacial and interglacial stages. Truly the author has embarked upon a Herculean task Anthropologists will not concur in some of his conclusions, but of this he is well aware He declares in the preface that, since his views on Australia's empty spaces were only accepted after a period of some twenty years, he "hopes that by 1944 his views as to race evolution and the relative status of Nordics and Alpines will be generally accepted !" Points such as these were raised at the time of his earlier publication "Environment and Race" and need not be discussed here

One could wish that Prof Griffith Taylor had given space to more details and discussion of racial matters The book suffers throughout from compression of this material, while some other subjects could well have been omitted (for example, geological features of the world in pre-Tertiary times). The author illustrates his points with numerous maps and diagrams, some of which are most illuminating He uses the polar projection to indicate the routes of migration from Central Asia, but his description of this map (p 30) requires revision. It is scarcely correct to speak of a *polar* projection as showing ". . . the central Asiatic land-mass with the three great continental 'peninsulas', America to the south-east, Eur-Africa to the north-east and Australasia to the north-west".

Parts 3 and 4 deal with conditions of settlement in Canada and Australia and with the influence of environment upon potential white settlement. The author is at his best in these sections of the book. Here also, however, the work is too condensed. The part dealing with Canada could well be expanded into a complete geography of the country. Prof. Griffith Taylor discusses the future of settlement in Canada and estimates that the Dominion could support another ten million settlers. This conclusion is misleading, however for it is based on figures from the Canada Year Book for 1934–35 for areas of occupied and potential agricultural lands which show a total of occupied land as 163 million acres with 198 million acres still available. It is known in Canada that these figures are a gross exaggeration. He makes a further calculation that the Dominion could conceivably support a population of somewhere about 100 millions. This total is based on population densities in Europe where he says Geographers are agreed that the population density is almost wholly controlled by crops and coal. He then asks How many people can Canada support using the same standards as those of Northern Europe including the use of coal to the same extent? The answer which he obtains namely 100 millions is admitted to be a mere approximation and subject to many other factors. Economists in Canada would no doubt have a good deal to say about this. Evidently Prof Griffith Taylor is ranging himself on the side of the optimists.

The book concludes with a chapter entitled Deductions and Suggestions, in which the author makes a well timed plea for the study of anthropology as a means of overcoming national and racial prejudice.

It is difficult to review a work such as this. It contains much that is interesting and stimulating but it is too rapid in its survey and yet is not free from repetition. Doubtless lack of integration is due in some measure to the incorporation of material previously published in the form of articles etc. The absence of a bibliography (except for a brief one on Australian settlement) is to be deplored. The serious student will require more detail while for the average reader there is too much although the author has lighter touches here and there such as the remark that of scenery— unlike the human subject the younger it is the more interesting'

S. W. ALTY

Evolution of the Printed Herbal

Herbals:
Their Origin and Evolution a Chapter in the History of Botany 1470–1670. By Dr Agnes Arber. A new edition, rewritten and enlarged. Pp xxiv + 326 + 27 plates. (Cambridge: At the University Press, 1938.) 21s net.

THE first edition of Dr Agnes Arber's delightful book on herbals has long been out of print and the appearance of a new and enlarged edition is therefore doubly welcome. It gives a clear account of the evolution of the printed herbal in Europe between the years 1470 and 1670, primarily from a botanical and secondarily from an artistic point of view. The first chapter deals with the early history of botany, touching on the philosophical treatises of Theophrastus (b 370 B C) and Albertus Magnus (d A D 1280), and the materia medica of Dioscorides, which for sixteen centuries was regarded as the most authoritative work on the subject.

The earliest printed herbals (fifteenth century) form the subject of the second chapter, some of them being in reality far more ancient than their dates of publication would suggest. They include the "Encyclopædia" of Bartholomæus Anglicus, the "Book of Nature" of Konrad von Megenberg, the "Herbarium" of Apuleius Barbarus, the "Latin Herbarius", the "German Herbarius" and the Ortus Sanitatis. The early history of the herbal in England is discussed in the third chapter which covers, besides English manuscripts of Apuleius Barbarus Banckes Herball" and the Grete Herball"

The botanical renaissance of the sixteenth and seventeenth centuries is described in Chapter iv (pp 52–145), which contains also sections on the 'Origin of Herbaria", and the 'Revival of Aristotelian Botany". Among the herbals dealt with are those of the German fathers of botany, namely, Brunfels, Bock, Fuchs and Valerius Cordus. No mention is made of the 'Botanologicon" of Euricius Cordus (1534) which though not strictly a herbal yet affords a vivid picture of the state of botany and pharmacy in Germany in the early sixteenth century, and should be taken into account in any history of the subject. Other sixteenth century botanists whose careers and herbals are reviewed are Dodoens, Clusius and Lobel (Low Countries), Mattioli and Colonna (Italy), Garcia de Orta and Monardes (Spain and Portugal), Gesner and the brothers Bauhin (Switzerland), Turner and Gerard (England).

An all too brief account of the evolution of the art of plant description is given in Chapter v. Here much research remains to be done, especially on the history of botanical morphology and terminology. The sixth chapter outlines the evolution of plant classification The evolution of the art of botanical illustration (Chapter vii pp 185–246) is treated much more exhaustively and to the general reader will perhaps be the most attractive portion of the book It is evidently based on many years of study

The doctrine of signatures and astrological botany are discussed in Chapter viii The chief exponents of the doctrine were Paracelsus (1493 1541) Porta (fl 1588) and William Cole (fl 1657) but it had its origins in remote antiquity a fact scarcely brought out by the author In Dioscorides we find for example that the seed of Εχιον (*Echium vulgare*) resembled a snake s head and that the root was an antidote for snake bites

Dr Arber points out in conclusion (Chapter ix) the incalculable debt which botany owes to medicine and a further debt to the arts of printing and wood engraving through which the traditional lore recorded in the manuscript herbals was embodied in the printed herbals which succeeded them In these the finest period as regards illustration was between 1530 and 1614 while classification nomenclature and description reached their zenith in Gaspard Bauhin s Prodromos (1620) and Pinax (1623)

There are three appendixes the first consisting of a chronological list of herbals between 1470 and 1670 the second being a list of historical and critical works consulted and the third forming a subject index to the second

Considering the book as a whole one cannot fail to be impressed by the versatility exhibited by Dr Arber in dealing with the varied aspects—morphological taxonomic historical bibliographical and æsthetic—of the evolution of the printed herbal There is only one criticism that may be made that some account should have been given of the works of the Arab physicians for example, Serapion the younger Mesuë and Avicenna who are so frequently cited in the Ortus Sanitatis and of certain other pharmaceutical works which were much consulted during the fifteenth and early sixteenth centuries such as the Luminare maius of Manlius de Bosco

The new edition is even more fully illustrated than the first containing 131 text figures 26 plates and a frontispiece showing a physician using a herbal after a picture by Adrian van Ostade (1665) The printing reflects credit on the Cambridge University Press and both text and figures show up better on the whiter paper employed in this edition The only misprint noticed is Isodorus (pp 301 305) for Isidorus T A S

Chemical Thermodynamics

Physical Chemistry
By Prof J N Brönsted Translated from the Danish edition (1936) by R P Bell Pp xv + 390 (London William Heinemann Ltd 1937) Price 12*s* 6*d*

IN Prof Bronsted s book which has been very well translated and is attractively printed the bias is towards thermodynamics Kinetic theory is also treated adequately and is used throughout the book to supplement the thermodynamics The rather abstract mathematical form of most of the book will tend to make it hard reading for many students There does not seem to be a single description of an experiment or a piece of apparatus in the book The thermodynamics is rather unusual, reminding one of Ostwald s energetics with its intensity and capacity factors and the suggestion that the second law can be deduced from the first This makes the derivation of the fundamental results longer than usual Once they have been achieved, the thermodynamic laws are applied by Gibbs s method which the author considers to be the easiest way of attaining simplicity and rigour

As might be expected the sections on electrolytes and the general theory of acids and bases are particularly full and interesting Although activity coefficients are used throughout the simple Debye Huckel equation is merely stated without derivation and its limitations are not emphasized A rather full treatment is given of the Bohr atom model but there is no mention of modern quantum theory or even of quantum numbers Reaction kinetics receive brief but clear treatment including the author s theory of the intermediate complex and there is a short account of reaction kinetics in gases from the point of view of critical energy The section on photochemistry is very brief A derivation of the phase rule is given with some very simple examples of its application A section on surface and colloid chemistry is written mainly from the thermodynamic point of view

The book will be found very interesting and stimulating by advanced students and by teachers For honours courses it will require considerable supplementing, and general students will mostly find it rather difficult

Lectures and Conferences on Mathematical Statistics

Delivered by J Neyman Revised and Supplemented by the Author with the editorial assistance of W Edwards Deming Pp ix + 160 (Washington Graduate School of the U S Department of Agriculture, 1938) 1 25 dollars

IN April 1937, Dr J Neyman, of the Department of Statistics, University College, London, delivered three lectures and was the leading speaker at six conferences, all held at the Graduate School of the United States Department of Agriculture, Washington The lectures were on the theory of probability, on probability and experimentation, and on the testing of statistical hypotheses The conferences dealt with randomized and systematic arrangements of field experiments, plant breeding, sampling in social problems analysis of time series, statistical estimation, and confidence intervals

The conferences were particularly valuable, as those present, many of whom were themselves eminent experts, put searching questions concerning difficult points In the verbatim reports of these questions and Dr Neyman s answers, the student will find a discussion of the relative values of alternative methods and of the relationship between alternative theories, which is almost unobtainable elsewhere The theory of statistical inference seems to be still in a very unsettled state, and the procedure recommended by one authority for conducting, for example, an agricultural experiment, is disapproved of by another authority Perhaps the differences are not always as serious as they at first appear Thus Dr Neyman s theory of confidence intervals cannot it is insisted, be reconciled with Prof R A Fisher s theory of fiducial probability, but so far the numerical results obtained have been the same, and it is possible that this will always be the case H T H P

Diesel Engine Design

By H F P Purday Fourth edition Pp xix + 520 + 4 plates (London Constable and Co , Ltd , 1937) 24s net

THIS is the fourth edition of a work which first appeared in 1920, and that the fourth edition is called for so soon indicates the value of this book

A comparison of the new edition with the last gives a very good idea of the progress made in Diesel engine design since 1928, as the author now finds it necessary to include new chapters dealing respectively with supercharging, torsional vibration, structural vibration, lubrication and noise all these subjects have come into the foreground in that interval

The title of the book is accurate, since the contents deal more with the art of design than with the sciences of the subject, although this is not to say that the latter are not taken fully into account , each chapter concludes with references to original papers which a reader may consult for a fuller treatment The reviewer concludes by repeating a remark made in reference to the third edition "Altogether any criticisms of the book relate only to details, and the author is to be congratulated on having written one of the best books of its kind" S J D

Strahlen um Uns

Von Heinz Tschelnitz Pp ii + 80 (Brunn, Prag, Leipzig, Wien Rudolf M Rohrer, 1938) 20 Kč

THIS little book is a survey of the chief questions of what is termed radiobiology Though it contains a certain amount of controversial matter and not a few speculations, it will interest both physicists and biologists by directing the attention of each to recent researches of the other connected with radioactive and electromagnetic radiations Evidence is adduced that all living creatures are continually subjected to the influence of such radiations For example, animals breathe ordinary air which contains radium emanation , their food and drinking water contain a small but definite amount of radioactive salts and cosmic rays play on them from above The organs of animals contain minute quantities of radioactive substances

The author supports the view of Stoklasa that a certain concentration of radioactive elements is natural and proper in any healthy living organism, but that any concentration in excess of this has a pathological effect He thinks that the relations of radioactivity to life are only just beginning to be understood, and he sees in the further study of the biological action of radiations the likeliest direction of progress in the understanding of life itself Though the reader may not agree with the author s views concerning the mitogenetic rays of Gurwitsch (cf NATURE 119 556 , 1927) the dependence of water divining and cancer on the emission of rays by the earth and other topics he will find the speculations entertaining if not always convincing

A Course of Pure Mathematics

By Prof G H Hardy Seventh edition Pp xii + 498, (Cambridge At the University Press, 1938) 12s 6d net

THE seventh edition of this famous text book first published in 1908, has now appeared It has been revised and reset The Cambridge Press mathematical printing is better than ever, the spacing and general lay out of the formulæ being excellent A large number of new examples from the Mathematical Tripos have been included The sections on the elementary properties of differential coefficients have been revised following the treatment in de la Vallée Poussin s ' Cours d Analyse" Apart from this, the general scheme of the book is unchanged The author says that the book was written at a time when analysis was neglected in Cambridge, and that if he were to rewrite it now it would be less like "a missionary talking to cannibals" and more like the usual ' Traité d'Analyse ' No one will regret that he has not made the change If we all live now on a decent mathematical diet it is due in no small part to the influence of this book They say that analysis has passed the peak of its popularity , but studies of this kind can never be out of date We believe that our successors will continue to derive the same inspiration from this book that it has given to us in the past thirty years E C T.

Geological and Archæological Aspects of South-Eastern Asia

By Dr H de Terra, P Teilhard de Chardin and Dr Hallam L Movius

MEASURING the age of man in terms of cyclic geological processes has always been a subject fascinating to the student of the Ice Age Unfortunately too little is known of such processes outside the glaciated regions to work out a stratigraphic scheme which might be applied to wider regions and yet this would be the solution to many important problems concerning the Quaternary and the prehistory of man In Asia for example mammalian fossils enable us to distinguish roughly between three Quaternary divisions but the fossil localities are scattered far and wide and the Quaternary formations traditionally passed over by governmental surveys are very imperfectly known

The wish to put our knowledge of the Ice Age in southern Asia on a geological basis led three years ago to the joint Yale Cambridge Expedition to Kashmir and India the results of which are now in process of publication by the Carnegie Institution of Washington From these results the Quaternary of India was seen to have been determined by diastrophic and climatic events of a very distinct nature permitting a detailed subdivision of the Ice Age Its periodic character was expected to make this stratigraphic scheme applicable to neighbouring regions or to supplement it by additional information In this way it was also hoped that the Cenozoic geology of India might become more clearly integrated with that of China which in turn would aid in the study of Early Man In discussing this plan with Father Teilhard de Chardin at the occasion of the symposium held in March 1937 in Philadelphia we planned to study the late Cenozoic geology and archæology of Burma Burma being favourably situated geographically between India and China held out considerable promise especially since Palæolithic tools had been found there recently by Mr T O Morris in association with terraces A few salient features of the Quaternary of Burma will be briefly outlined below Father Teilhard de Chardin co operated with the expedition during the four months of field work and the third author carried out the archæological work in close association with the geological party

The expedition was undertaken under the joint auspices of the Academy of Natural Sciences of Philadelphia and the Peabody Museum of Harvard University Following the field season in Burma, all members of the expedition proceeded to Java There during the month of April we had the opportunity of visiting under the expert guidance of Dr von Koenigswald the sites at which fossil man and Palæolithic implements had been discovered in recent years

TERRACE SYSTEM OF THE IRRAWADDY VALLEY

In the Irrawaddy Valley our investigations were carried out chiefly between Magwe and Nyaungoo near Pagan but various excursions were made also along tributary streams leading westward to the Arakan Yoma Mountains The most characteristic features of the Irrawaddy terraces are as follows

(1) They are superimposed on the Irrawaddy Series a folded and peneplained river formation the upper part of which contains a mammal fauna analogous to that of the Upper Siwaliks of India

(2) Occupying an old valley the terraces are mainly composed of coarse boulder bearing gravels in which three distinct stages of aggradation could be differentiated

The highest terrace gravel is preserved in a group of hills situated in the oilfield of Chauk and some 350 ft above the stream The size of its pebbles depicts an ancestral Irrawaddy much more powerful than the present river An oldest lateritic soil mantle in the adjoining hills appears to be connected with this stage which clearly was a period of greater rainfall (At present this region belongs to the dry belt of Burma with 60–70 inches of annual rainfall which falls almost entirely between the months of June and September No lateritic soils are formed here at present) At one place the highest terrace was found to contain some flaked pebbles of fossil wood and silicified tuff This terrace is strongly tilted

The second and third terraces lie some 180 ft and 100 ft respectively above river level and are associated with a thick series of red gravel and sand In this was found near Mingun opposite Mandalay a Middle Pleistocene type of fauna (with *Elephas namadicus*) and farther downstream an Early Palæolithic industry (see under Archæology) A long interval of erosion and of aridity preceded the deposition of this second river drift, and then a valley was formed with ferruginous soil caps containing the earliest prehistoric industry The second river gravel buried the valley but prehistoric settlements continued as indicated by the wealth of rolled Palæolithic tools in the basal gravels Again this was a period of increased weathering and water supply during which the adjoining highlands released thick fans of red earth on to the second terrace

The fourth terrace is made of the third type of gravel which is generally less coarse and more sandy A somewhat advanced type of Palæolithic was found in this The fifth terrace (25 ft) approaches in composition the recent river deposit and may be post Pleistocene in age

(3) The terraces are associated with soils corresponding to periods of greater and lesser rainfall The first and second type of gravels are connected with lateritic soils found on the adjoining land surface From here red earth was washed into the valley especially during formation of the second terrace in which fine grained red sand merges laterally into lateritic slope wash deposits Increasing aridity is indicated by the presence of loessic soils on the fourth terrace This soil is of yellow or pinkish colour mostly structureless and was drifted in the manner of true loess on top of the third terrace the erosional surface of which was thus again buried The composition of this fourth terrace however proves that this must have been a major and prolonged fill stage

(4) The Irrawaddy terrace system is of regional extent for it was found also in the adjoining Shan Plateau in the reaches of the Namtu and Salween Rivers

The interpretation of these features leads to conclusions which are of importance to both geologist and archæologist It is interesting to note the great resemblance of this terrace system with that found in North West India both in respect to the number and the nature of the physiographic cycles In both regions the terrace formation began in the Middle Pleistocene because of the then established relative stability in the Himalayan foredeeps in which the Early Pleistocene beds are generally strongly folded In India three major fill stages could be correlated with the three last Himalayan glaciations and terraces were ascertained some 150 miles distant from the limits of glaciation In Burma the distance from the glaciated tracts is more than double that amount but here the soil records indicate the impact of corresponding climatic cycles in the nature of Pluvial and Interpluvial stages which were apparently superimposed on cyclic diastrophic processes It is probable that in the upper Irrawaddy Series are hidden two Early Pleistocene sub stages which as yet do not readily permit of the same detailed analysis These earlier beds have yielded certain palæontological data which are likely to throw new light on their stratigraphic position

PALÆONTOLOGICAL ASPECTS OF THE PLEISTOCENE IN BURMA

The Upper Irrawaddy fauna has been known for some time especially through studies by Noetling and Pilgrim and lately Colbert has analysed it anew with the collection of Dr B Brown The vertebrate fossils collected by us can only confirm the view that an Upper Siwalik type of fauna is represented in these beds In our material forms such as *Leptobos Bubalus Stegodon* primitive elephant and horse are most prominent together with other types of lesser stratigraphic significance

It is important to note that these beds have for the first time yielded both freshwater molluscs and plant remains Their state of fossilization as well as the type of freshwater fauna represented clearly indicate an Early Pleistocene age for most of the Upper Irrawaddy series Moreover the overlying terrace gravels contain a Middle Pleistocene type of fauna (*E namadicus Bos* cf *namadicus Hippopotamus*) reminiscent of the Narbada Pleistocene of peninsular India Such a succession would be difficult to comprehend if the underlying beds were to represent the late Pliocene

Of special interest was the discovery of fossiliferous fissure deposits in the Shan Plateau near Mogok Except for a skull of *Ailoropus* nothing was known of this fauna which is likely to throw new light on former faunistic relationships of the Indian with the Chinese mammal world The presence of *Stegodon Flephas namadicus Bos Rhinoceros Cervus Hystrix* links this fauna with that typical for the limestone fissures found in the neighbouring provinces of China

CORRELATIONS WITH SOUTH CHINA

The conclusions arrived at by Teilhard de Chardin in regard to existing analogies between the late Cenozoic of Burma and China can only be mentioned very briefly in this report Such analogies are striking mainly (*a*) in the late Pliocene lake deposits of the Shan Plateau (*b*) in the Early and Middle Pleistocene gravel formations (*c*) in the fissure deposits All three are practically continuous between Eastern Burma and the Yangtse basin They must therefore be contemporary and express the same series of diastrophic and climatic changes over the same geological unit Hence the terraces of the Yangtse may be linked to those found in India and Burma and the possibilities of covering under a single stratigraphic and physiographic scheme the late Cenozoic history of the whole south and central Asiatic Mass becomes an assured possibility'

ARCHÆOLOGY OF BURMA

By Hallam L. Movius

At several localities in Upper Burma fairly extensive sites yielding Lower Palæolithic tools were discovered In all cases the implements are rolled and are associated with the main terrace (*T*–3) gravels of the Irrawaddy Valley This horizon may be assigned on palæontological grounds to the Middle Pleistocene The principal sites are at Yenangyaung Chauk and Nyaungoo (near Pagan), although further collecting was also done at Pakokku and at Pauk in the Yaw Valley The implement types, which include chopping tools, crude scrapers, a few flake implements and cores, are made either of silicified tuff or fossil wood Hand axes are completely absent, a fact which seems to indicate a more definite association with an Eastern Asiatic focus than with an Indian one Typologically the closest analogies to the Lower Palæolithic of Burma are found at Patjitan in Java, but Dr von Koenigswald's extensive collection from this latter region includes hand axes, in addition to an abundance of Burmese forms Thus at present the cultural affinities of the Burmese Palæolithic are not altogether clear, although the Java connexion cannot be denied Perhaps both are derived from a common source somewhere in South China, or perhaps in Malaya

Since an entirely new Lower Palæolithic complex is presented by the Burmese material, it has been named the 'Anyathian' after the coloquial Burmese for an Upper Burman (ăn ya thă) The early Anyathian is represented by two phases—phase 1 from the basal cemented gravels of *T*–3, and phase 2, which is derived from the overlying uncemented material Only crude chopping tools, made of roughly tabular blocks of silicified wood, worked on the upper surface of one end, are found in the earliest phase The implements are all heavily patinated and rolled In phase 2, however, the forms are more varied several types of chopping tools, crude flake implements, and nuclei occur The former include finely made core implements with alternately flaked cutting edges while the latter are extremely coarse and are devoid of Levalloisean or Clactonian influences In Burma, therefore, the chopper rather than the hand axe is the type Lower Palæolithic implement

The Late Anyathian is found unrolled on the surface of *T*–3 and slightly rolled in the Upper Pleistocene gravels of *T*–4 It seems to be essentially a development from the Early Anyathian, although the implement types are small and on the whole more specialized They include many new forms — disk shaped end scrapers, side-scrapers, blades, and even steep scrapers of Upper Palæolithic type Chopping tools of the Early Anyathian are also present, which makes it difficult to determine whether this culture represents an innovation or an indigenous development brought under influence from an Upper Palæolithic centre outside the region

No Mesolithic has yet been found in Burma although the cave region of the Southern Shan States was extensively explored However, abundant Neolithic material was collected everywhere on the surface of the higher terraces, as well as *in situ* associated with polished stone axes, at Minbu and Kyaukpadaung Pottery from the latter locality confirms the Neolithic dating of this complex, originally described by Noetling as 'Eolithic'', and more recently by Morris as Upper Palæolithic '

Thus a chronological basis for the Burmese Stone Age has been established, and as Dr de Terra points out, this archæological sequence is substantiated by stratigraphy Burma has, therefore, added another link in our chain of knowledge concerning the development of early man in south east Asia One salient fact however, which emerges from a preliminary study of the Anyathian, is the absence of influence from southern India This is significant in the light of Dr von Koenigswald's discoveries in Java, for if the culture of Patjitan is connected with India, traces of this connexion must inevitably exist in Burma However, with the exception of the Javanese hand axes, the Patjitanian and the Anyathian are almost identical These facts, therefore, suggest that we are dealing with a new centre of Lower Palæolithic development in the Far East to which the orthodox European classification cannot be applied

EXCURSION TO JAVA

Our field season in Burma closed at the end of March, when all members of the expedition proceeded to Java Here we visited, under the guidance of Dr von Koenigswald, the most important places where either fossil man or Old Stone Age cultures had in recent years been discovered It is impossible to do full justice here to the truly remarkable wealth of information which Java holds in regard to Quaternary geology and early man

Especially interesting to us was the Solo Valley with its terraces containing Palæolithic industries and the skulls of *Homo neanderthalensis solœnsis* Oppenoorth One cannot help but feel that a physiographic survey of this region will furnish a key to a more detailed stratigraphy which so far has been founded mainly on palæontological data Here it became evident that the Quaternary of Java differs in many respects from that found in continental Asia , for one thing, volcanism has here introduced processes of sedimentation the periodic character of which is not readily recognized Also, the climatic records of the humid tropics differ altogether from those found in more arid latitudes, and the effect upon fauna and sediments is such as to make direct correlations with the Quaternary of the Asiatic mainland less readily available than was at first anticipated

The new site of the *Pithecanthropus* skull and mandible near Sangiran north of Solo assures beyond doubt the Middle Pleistocene age of this fossil Its stratigraphic location was in the lower portion of the Trinil beds', which are here overlain by some 150 ft of Middle and Upper Pleistocene fossiliferous strata, all of which are clearly exposed in one section Especially clear is the position of the infant skull of *Homo modjokertensis* v Koenigswald, near Modjokerto in eastern Java Despite the relatively shallow depth at which the skull was discovered (3 ft), it was evident that in the absence of soils and terraces, nothing could have obscured the true location and stratigraphy of this fossil Its age, according to von Koenigswald, is Lower Pleistocene because of its association with certain mammals such as *Hippopotamus antiquus* and *Cervus zwaani*, as appear to be ancestral to others found in the Trinil fauna

---

In concluding this report, I wish to express our sincerest appreciation for the financial support which the American Philosophical Society, Harvard University and the Carnegie Institution gave to this undertaking We also wish to thank the Director of the Geological Survey of India, and the members of the Geological Department of Burma and our colleagues in Java for the friendly co operation extended to us

International Committee on Social Relations of Science

THE Committee on Science and its Social Relations (C S S R) instituted by the International Council of Scientific Unions, in May of last year, held its second meeting in Paris this year, when a number of organizational questions connected with the work undertaken were discussed From a report prepared by the secretary the following points may be mentioned

As stated already (NATURE, 140, 983 , 1937 141 723 , 1938), the main work of the C S S R for the present is to collect materials for the preparation of a report and of bibliographies on the social relations of science, to be presented at the next meeting of the International Council in 1940, and thereafter it is hoped, to be printed for wide circulation For the execution of this plan the C S S R has applied to the national academies, or other nationally representative bodies of various countries, and to a number of international scientific organizations, with the request to assist it in its task by supplying information, and by appointing correspondents who may gather around themselves other men of science interested in the work of the C S S R , so as to form local or special groups co operating with the latter The Royal Society of London has nominated Prof F E Weiss as its correspondent, and a subcommittee, with members for physics, chemistry, engineering and, if possible, also for medicine and for some other branches of science, is being formed

To guide correspondents in furnishing their communications to the C S S R , it was proposed to draw up questionnaires, indicating the points which should be judged to come within the scope of the inquiry The preparation of these questionnaires was a kind of experiment as in a way they should form a programme for analysing the manifold influences that science and human society exert upon each other Various points of view presented themselves according to which topics might be classified , on one hand attention should be given to the influence on social relations emanating from the application of a number of definite recent scientific discoveries , on the other the influence of science on the outlook of men and women should be considered The relation between certain subjects and the life of human society further could be investigated according to national points of view, or from that of the various domains of science themselves

It was decided, therefore, in the first place to draw up a general questionnaire', intended as a guide for the use of correspondents of the nationally representative scientific organizations of the various countries The subjects listed in this questionnaire have been grouped under three headings, as follows (1) the meaning of scientific research for the development of our world picture—to be understood not only in the philosophical sense, but also in the sense of the set of ideas with which the public (in its various forms of appearance) is operating , (2) the influence of the applications of scientific work upon human society, the transformations that are induced by them and the adaptations which are required in consequence , (3) reactions of human society upon scientific work

In connexion with the experimental character of the work, it may very well appear that other subjects besides those listed will have to be introduced, or that various questions should be framed differently It must be remarked also that owing to the structure of the International Council in which the medical and engineering sciences agriculture sociology and economics have no representation problems referring to the latter subjects provisionally have been left aside the more so as these subjects require a different treatment and should not be attacked before some experience and contact with the organizations specially created for them might have been obtained Only a few borderland problems have been touched upon here and there

In asking the national correspondents to give attention to the general questionnaire it is not expected that they should treat all the subjects listed in full The extent to which information can be supplied will depend upon the measure in which attention is given to science in the various countries and thus may largely differ from one country to another It is possible also that certain questions may not be directly applicable to the conditions found in some countries It has been suggested that correspondents leave aside questions which appear to them to bear no relevance to the situation in their countries and either restrict themselves to the other questions or give information in a more independent form

It should be emphasized however that the C S S R hopes to receive information concerning the many points of view which may be developing in various countries Along with the list of questions for national correspondents a series of questionnaires has been drawn up in which the subjects are considered from the points of view of the particular branches of science These questionnaires are not intended for consideration by the national correspondents but are forwarded to correspondents of international scientific organizations In part they contain some of the same topics as had been brought together in the general questionnaire but for a number of subjects more detailed problems have been noted These questionnaires thus far have been devised for mathematics astronomy mechanics physics chemistry biology geophysical sciences geography

The C S S R has also requested correspondents to supply a bibliography or a list concerning summarizing and reviewing or abstracting work that is being done with respect to scientific publications either in their country (in the case of national correspondents) or in the branch of science represented by them (in the case of correspondents from scientific organizations) Such lists should give the names of progress reports collections of abstracts of scientific literature names of abstracting and reviewing organizations science press service where this is present etc

The C S S R hopes that along with the help given by correspondents and their sub committees co operation may be obtained and organized with other bodies occupied with similar problems

At the present moment there seems to be a possibility of coming into contact with the British Association for the Advancement of Science—at the forthcoming Cambridge meeting the Council of the British Association will present a scheme for the establishment of a special Division for the social and international relations of science (see NATURE July 30 p 195) and with the American Association for the Advancement of Science

Attempts are being made to secure the foundation of an organization for the study of the social relations of science also in Holland Such organizations which should be formally wholly independent of the C S S R can perform much useful work by promoting special investigations on problems of importance for the country where they are working for which purpose—assuming that the necessary financial means can be found—research students for example might be appointed At the same time they could assist the correspondent of the C S S R in his work of collecting information according to the general questionnaire while on the other hand the C S S R can help in establishing international contacts and in correlating results brought forward from different countries Moreover such organizations may find the possibility of considering sociological and economic problems which fall outside the scope of the I C S U and the C S S R

It is expected finally that assistance also may be obtained from individual scientific investigators who take an interest in the work of the C S S R Apart from the help that may be asked from them with reference to particular scientific topics there are the following points concerning which views or information often can be given better by individual persons than by official organizations

(*a*) The part played by scientific thought in the outlook of various social groups

(*b*) The forms in which scientific workers and their work are involved in the various struggles and conflicts of human society

(*c*) The forms in which the consciousness of a social responsibility of science and of scientific workers is taking shape

Scientific workers who desire to give information or to express views on points coming under the scope of the Committee s work are requested to communicate with the correspondent for their country or their branch of science or directly with the secretary of the C S S R (Prof J M Burgers van Houtenstraat 1 Delft) The secretary of the C S S R also will be glad upon application to forward copies of the report or of the questionnaires to persons interested

Water Development Schemes in the United States*

THE National Resources Committee of the United States Government, the membership of which includes the Secretaries for the Interior for War for Agriculture for Commerce and for Labour has issued an important document on Drainage Basin Problems and Programs (1937 Revision) which has been prepared by the Water Resources Committee with the co operation of local, State, regional and federated organizations It is a comprehensive review of suggestions emanating from forty five Drainage Basin Committees, themselves nominated by 'Governors and State Planning Boards, including field men from interested Federal bureaus It will thus be seen that the recommendations are based on a wide spread representation of national interests

The report was commissioned by the President and constitutes a revision of the report to Congress on February 3 1937, rendered necessary by recent developments, including fresh problems and new standards of treatment An amended programme, accordingly, has been prepared covering a series of specific projects to be undertaken within a 2–6 year period, at an estimated cost, amounting in the total to 891 091,000 dollars, with a "weighted average" per year of 200 624,000 dollars This weighted annual average compares with more than 180,000,000 dollars recommended in the President's 1939 Budget for the same classes of work During the last six years the Federal Government has expended more than 1,300,000,000 dollars on works of a similar character

Foremost in the report comes the subject of flood control, which in the United States is a matter of the most serious public concern One has only to recall the devastation and loss of life caused during the floods of recent years in the Mississippi and Ohio river valleys to realize how vital this matter is to a vast mass of the population Unfortunately, the problems involved are so complex that, as yet, they are inadequately explored, and it is felt that it would be most unwise to authorize any additional general flood control plan until more trustworthy information is obtained An early inauguration of surveys and investigational studies of a comprehensive character is urged and budgeted for at a cost exceeding 260 million dollars

The reclamation for agricultural purposes of extensive regions of arid and semi arid country requires continued attention Works are already authorized and in hand to the extent of upwards of 600,000 000 dollars but further surveys are needed for future planning and development West of the 100th meridian, there is a vast domain of no fewer than 700 million acres where agriculture can make no progress without artificial irrigation The outlay required is put at nearly 300 million dollars Problems of flood control policy naturally involve a consideration of the allocation of cost among the various scattered communities in low lying regions subject to inundation in fair proportion to the incidence of benefit and of ability to pay and this is a matter which can only be settled by prolonged negotiation

Water power is an important consideration in the United States, where there are very considerable reserves ready for exploitation The energy produced is utilized in many directions for power, heating and lighting Water power has within the past half century furnished 3–4 per cent of the total energy derived alike from mineral fuel and water and the report states that "despite the fact that the nation now depends and in future must depend largely on its fuel resources, its water power is of great value and presents great opportunities in the co ordinated development of water resources" Some of the more important undertakings in hand, as the Boulder Dam on the Colorado River, the Bonneville and Grand Coulee Dams on the Columbia River, and the series of developments in the Tennessee Valley have already been described in NATURE (139, 738, 823, 986, 1937)

The other subjects dealt with in the report, which runs to more than 150 pages, are so many and so varied that it is not practicable to touch upon them all within restricted limits of space A mere enumeration shows that they include navigation, soil conservation, beach erosion control, projects for agriculture and grazing, pollution, recreation and wild life, hydrological data and investigations and multiple purpose projects

The report concludes with an expression of the conviction of its members that "a National Planning Agency should have as one of its chief duties the continuous development of broad plans for full use of our water resources in relation to human needs and social objectives" This clear and explicit declaration of policy might with advantage be adopted in other countries, and every credit is due to the United States for setting so conspicuous an example of enterprise in the exploitation of its own supplies

Obituary Notices

Dr. J. W. Mellor, C.B.E., F.R.S.

On May 24, science suffered a great loss by the death of Joseph William Mellor, a man of remarkable attainments and outstanding achievement.

Born at Huddersfield in 1869, Mellor was taken by his parents to New Zealand when ten years old. During his youth he worked in a boot factory and took classes in the evenings at the Dunedin Technical College. At the age of twenty-five years he was awarded a scholarship at the University of Otago. After graduating and serving as a science lecturer at an agricultural college he was awarded an 1851 Exhibition, which took him to the University of Manchester in 1899. Under H. B. Dixon, for whom he had the highest regard, he completed a number of researches, perhaps the most important being investigations into the combination of hydrogen and chlorine.

On leaving Manchester, Mellor went to North Staffordshire, and, after a short period as science master at the Newcastle (Staffs.) High School, began his long association with the ceramic industries on his appointment as lecturer in pottery manufacture in Stoke-on-Trent.

At the commencement of his career in ceramics, Mellor worked under some difficulties, and it was due, in no small measure, to his initiative that the present North Staffordshire Technical College was built in 1914. He was appointed the first principal of the Pottery Department. As a teacher he was very popular with his students, and, in this capacity alone, he rendered great service to the local pottery industry. There can be no doubt that his early struggles gave him a deep insight into the difficulties of his evening students. Shortly before his death he said, "I think that I spent some of the happiest years of my life with those early students".

Mellor's great friendship with Bernard Moore, the eminent potter, played a conspicuous part in the progress of clay technology in Great Britain. He was associated with the work of the Ceramic Society about three years after its formation, becoming honorary secretary in 1905, a position he held until his death. He raised the status of the Society from a purely local association to that of an international institution. He extended its field to include refractory materials and clay building materials, as well as pottery. The Society's present eminence is a lasting testimony to his high endeavour.

Mellor wrote more than a hundred papers on ceramics, the first in 1904 and the last he completed two months before his death. Covering a very wide field, his researches into the constitution of the clay molecule and the properties of glazes are, perhaps, the most important. His papers on "The Crazing and Peeling of Glazes" and "The Durability of Pottery Frits, Glazes, Glasses and Enamels in Service" appeared in 1935 and gained world-wide appreciation. He was quick to realise the importance of refractory materials to the well-being of an industrial nation. He made contact with the manufacturers and users of these products, and, in 1909, was closely associated with the formation of the Refractories Committee of the Institution of Gas Engineers, which has been responsible, in Great Britain, for pioneer work into the properties of refractory materials. This association developed, and, in 1919, Mellor was largely instrumental in establishing the British Refractories Research Association under the ægis of the Department of Scientific and Industrial Research. As its first director of research, a position he held until 1937, he enlisted and retained the support of manufacturers and users of refractory materials, added great distinction to the work of the Association, and founded "The Mellor Laboratories", the present headquarters.

To his great scientific attainments, Mellor added a singular literary ability. 1937 saw the completion of his monumental work, "A Comprehensive Treatise on Theoretical and Inorganic Chemistry" in sixteen volumes. He received, during his lifetime, unstinted praise for this remarkable effort. To his few intimate associates, the completion of these volumes is almost beyond comprehension. They know that he wrote every word and every reference.

As a student, Mellor found it impossible to follow the many developments in chemistry without a good working knowledge of higher mathematics. His habit of making full notes of all his difficulties led him to consider writing a book on the application of higher mathematics to chemistry. Putting the suggestion to H. B. Dixon, he was advised to convert his ideas into words, and thus, in 1902, his first book, "Higher Mathematics for Students of Chemistry and Physics", appeared. Shortly afterwards he set to work on his "Chemical Statics and Dynamics", which was published in 1904, and later he confessed that the writing of this book had given him very great pleasure. His "Modern Inorganic Chemistry", a book of distinct individuality, had a remarkable vogue in the whole of the English-speaking world and rightly so. As a result of his early work in ceramics, in 1912 he completed "A Treatise on Quantitative Inorganic Analysis", which remains a standard work on silicate analysis.

In his youth, Mellor had considerable physical strength, and was a powerful swimmer. He was an enthusiastic and highly accomplished chess player. His sense of humour delighted all who knew him, and he combined with this considerable ability as a cartoonist. His book of cartoons, "Uncle Joe's Nonsense", revealed his ever-youthful spirit.

Mellor was a man of indomitable courage, profound wisdom and experience. He had remarkable astuteness. Of his pertinacity and capacity for sustained exertion there is abundant evidence. He could pursue a preconceived course of action with a tenacity of purpose rarely achieved. He had a vivid appreciation of loyalty and friendship To those who knew him, his supreme loyalty was, indeed, his greatest attribute. He was respected by all and much more than respected by those who were privileged to know him intimately A T. G

Dr. W. C. Willoughby

WE regret to record the death of the Rev. Dr W C Willoughby, an authority on the Bantu of South Africa, who died at Birmingham on June 19 at the age of eighty one years.

William Charles Willoughby was born on March 16, 1857. He was the son of Richard Willoughby of Redruth, Cornwall, and was educated at Tiverton and Springhill College, Birmingham In 1882, having been ordained a Congregational minister, he joined the Central African Mission of the London Missionary Society, but was compelled to return home after twelve months service owing to ill-health. His interest in Africa, however, continued unabated, and in 1893 he was appointed by the London Missionary Society to deal with difficulties which had arisen at Phalapye, the headquarters of Khama, paramount chief of the Bechuana After the Matabele War he was chosen by Khama and the two chiefs, Bathoen and Sebele, to act as their adviser in their appeal to the British Government in relation to the proposal to hand over the Bechuanaland Protectorate to the Chartered Company Largely owing to his efforts their appeal, presented by them in person in London, was successful

Willoughby remained in Bechuanaland for eight years and was then selected to act as first principal of the Tiger Kloof Educational Institution, which he had founded near Vryburg, Bechuanaland Here he instituted a very successful scheme of training in industry, craftsmanship and teaching for young African men and women Willoughby retired from Tiger Kloof in 1917, and two years later was appointed professor of African missions in the Kennedy School of Missions, Hartford, Connecticut He held this chair until 1931, when he retired, receiving the honour of D D. Dr Willoughby was widely recognized as an authority on Bantu anthropology He was a member of the African Races Committee from 1900 until 1908, and had been a local correspondent of the Royal Anthropological Institute since 1905 He was the author of "Native Life on the Transvaal Border" (1900), "The Soul of the Bantu" (1928), and "Race Problems in the New Africa" (1923). In these he showed a sympathetic insight into the mental qualities of the South African native, and though fully alive to the desirability of developing native culture, recognized the danger of attempting to impose Western civilization on native tradition.

Dr. L. Lilienfeld

LEON LILIENFELD, whose death occurred quite unexpectedly at Milan on June 6 through pneumonia contracted whilst engaged on the industrial application of his latest inventions, commenced his professional career as a medical man. A growing interest in cellulose led him to abandon medicine and devote himself to research work on this material. In 1912 he produced new derivatives of cellulose, namely, various cellulose ethers having very widely different properties and capable of diverse applications The Great War interrupted these activities and Lilienfeld was engaged on X-ray work in the Austrian army. He wrote a book embodying all his experiences which even to-day is regarded as a standard work in this branch of medical research

After the War, Lilienfeld returned to his work on cellulose and evolved a process by which viscose can be spun into a thread having a tenacity far greater than that of any rayon thread known at that time Naturally, this work brought Lilienfeld into prominence not only with the rayon world but also far beyond Afterwards he returned to the field of cellulose ethers, which he perfected in their application to rayon, films, etc. In this connexion it is interesting to note that Lilienfeld showed that certain ethers when taken internally counteract the effects of alcohol

Much of the work of Lilienfeld is embodied in numerous patent specifications, which demonstrate with what extraordinary energy and thoroughness he pursued his investigations

Those who knew Lilienfeld will learn of his death with deep regret, and many have lost in him a friend of great charm and generosity

Rev. E. Burrows, S.J.

WE regret to record the death of the Rev Father Eric Burrows, Assyriologist and cuneiform scholar, who was killed in a motor accident near Oxford on June 23 Educated at Felstead and Keble College, Oxford, Eric Burrows joined the Order of Jesuits in 1915 He studied Assyriology under the late Prof. S P Langdon, specializing in cuneiform epigraphy, and had already established a reputation as an authority upon the early religious and legendary literature of Mesopotamia, when in 1926 he became attached to the staff of Sir Leonard Woolley as epigraphist in the excavations at Ur. He worked with the Ur expedition in the field in each successive season until 1930. Much of his work is still unpublished, but his contributions to the official volumes on "The Royal Tombs" dealing with the documents of the early dynastic period of Ur, and his "Archaic Texts" are accepted as the standards of reference on archaic palæography and the beginnings of cuneiform.

WE regret to announce the following deaths:

Prof. G. W. Cavanaugh, emeritus professor of chemistry in Cornell University, on July 2, aged sixty-eight years.

Capt. F. S Barnwell, O B.E., chief designer of the Bristol Aeroplane Company, a pioneer in British aviation, on August 2, aged fifty-eight years.

Prof. L. Frobenius, who led numerous expeditions to different parts of Africa, and was a great authority on African culture, aged sixty-five years.

News and Views

Geology and Archæology in South-Eastern Asia

IN another column of this issue of NATURE (see p. 275) there appears a communication from Dr H. de Terra, Dr. H L Movius and Father Teilhard de Chardin of far-reaching significance for the study of early man in Eastern Asia. The investigations of the joint Yale-Cambridge expedition to northern India, of which Dr de Terra was leader, having established by the examination of the quaternary deposits a detailed subdivision of the Ice Age in that region, it was hoped that a like investigation of the quaternary gravels of the Irrawaddy Valley, in view of their central situation, might afford evidence for the integration of the cenozoic geology of southern China with that of India. Inferentially, it is obvious, such an integration would be of crucial value in establishing the chronological relation of the evidences of early man in the two regions In 1937 an expedition under the joint auspices of the Academy of Sciences of Philadelphia and the Peabody Museum of Harvard University, with Dr de Terra again as leader, entered upon the investigation of the quaternary deposits of the Irrawaddy Not only was the expedition successful in establishing the resemblance of the Irrawaddy terrace system with that found in north-west India, while the soil records indicate the impact of corresponding climatic cycles, apparently superimposed on cyclic diastrophic processes, but it was also able, thanks to the co operation of P Teilhard de Chardin, the distinguished authority on the quaternary geology of China, to demonstrate as sufficiently assured the possibility that the late cenozoic history of the whole of the south central Asiatic mass will be covered ultimately by a single stratigraphic and physiographic scheme At the same time the subsequent visit of the expedition to Java made evident that the quaternary of that area differs in many respects from that of the mainland and that direct correlation will be less readily available there than was anticipated.

THE palæontological evidence is of special interest in relation to the development of recent theory in the Chinese field. The most significant feature is the discovery of a previously unknown fauna in the fissure deposits of the Shan plateau, which, it is said, may prove to throw light on former faunistic relationships of the Indian with the Chinese mammal world This fauna of the Shan plateau is linked with that typical of the limestone fissures of the neighbouring provinces of China, which figures prominently in P. Teilhard de Chardin's recent researches. The archæological evidence, as Dr. Movius shows, is no less important. It presents an entirely new lower palæolithic cultural complex, for which the name "Anyathan" is proposed. In this culture the type lower palæolithic implement is the chopper, rather than the hand-axe. It persists into late Anyathan side by side with many new and more specialized forms, making it difficult to decide whether this culture is to be regarded as an innovation, or an indigenous development under outside influence It is especially to be noted, however, that although a chronological basis for the Burmese stone age has been established, substantiated by stratigraphy, and Burma thus affords another link in our chain of knowledge concerning early man in south-east Asia, the really striking fact which emerges is the absence of influence from southern India. There is, however, except in one respect, close resemblance with the recently discovered Patjitanian of Java. These facts, Dr. Movius concludes, are such as to suggest that we are dealing with a new centre of development in the Far East, to which the orthodox European classification cannot be applied

Composite Aircraft Development

THE seaplane upper part of the Short-Mayo composite aircraft has flown the return journey across the Atlantic It was able to get off the water from the American side under its own power, owing to the much smaller load of fuel required for the west to east journey with its constant following winds Now that the success of the idea is established, plans are in hand for a new design on similar principles incorporating all the modern developments in aerodynamics, such as constant speed airscrews, retractable undercarriage, slots and flaps as aids to lift and control, etc The body will probably be arranged principally for mails, with a few passengers

ANOTHER composite aircraft of somewhat different principles is proposed by Mr. A Plesman, of the K L M, Royal Dutch Air Lines The lower component in this case is practically a flying undercarriage that can make contact as well as detach itself while the upper main machine is in the air. Thus in normal flying the aircraft will have no undercarriage, saving the consequent weight and drag. This proposal is essentially different to the Short-Mayo design, in that it does not add the extra wing area and engine power for the take-off when the machine is heavily loaded with fuel and oil at the commencement of a long flight. Launching by catapult, or some such form of acceleration, is proposed to deal with this difficulty The scheme presupposes no necessity for any unexpected forced landing en route, a not unfair assumption with modern engine reliability, and the use of multiple-engined machines. In any event, a successful landing on the sea, in the case of a trans-ocean flight, would be of little value, as an average aircraft would be too fragile to remain afloat long under any but the most ideal of conditions.

New Cooling System for Aero-Engines

Messrs Rolls Royce have introduced a new system of water cooling under pressure on their Merlin IV engine This is similar to the usual atmospheric one, but is closed and provided with loaded valves, so that the boiling point of the water under pressure is raised The many recent developments in metallurgy and lubricating oils have made it possible for the internal combustion engine to function at higher temperatures and thus to increase thermal efficiency in addition to the obvious advantage of using smaller radiators with both less drag and weight The more general method up to the present of maintaining the engine at the higher temperature permissible has been to use liquids with higher boiling points Ethylene glycol is the most generally used in Great Britain, but this has objections in its corrosive effect upon parts of the cooling system, especially the inevitable joints if a substance such as a rubber or leather compound is used Extra cost, and the necessity of carrying a supply of the special liquid are also points against such preparations The new radiator and cooling system fittings may need to be somewhat more robust for dealing with pressure, but this is not altogether a disadvantage in that the more solid construction will add to its reliability Weakness due to flimsy construction has often been typical of the older water cooling systems It is reported that these engines with their new cooling will be fitted to the Armstrong Whitworth Whitley the new R A F bomber now coming into production

British Speleological Association

At the third annual conference of the British Speleological Association which opened at Giggleswick School, Yorks, on July 30, Dr R R Marett, rector of Exeter College, Oxford was elected president in succession to Sir Arthur Keith, who has held that office since the foundation of the Association As an anthropologist Dr Marett is perhaps best known for his studies of the religion and psychology of primitive peoples, but his connexion with the archæological exploration of caves is of long standing In 1911 he described before Section H of the British Association the excavations in the cave in St Brelade's Bay, Jersey, carried out by himself and other members of the Société Jersiaise, which resulted in the important discovery of a tooth of Neanderthal man in association with Mousterian implements

The conference of the Speleological Association was declared open in an original and appropriate ceremonial by Mr J A Slingsby chairman of the Governors of Giggleswick School At a business meeting of the Association it was reported that the survey of underground waters in Yorkshire, Derbyshire and Somersetshire is being continued, and that considerable progress had been made in listing the caves of Britain in which archæological material had been found in the past In addition to papers presented for discussion at sectional meetings, the proceedings included visits to a number of museums in Settle and neighbourhood containing material illustrating and recording the results of cave exploration, and visits to the caves themselves, including the Victoria and Jubilee caves, long well known for their archæological importance and Gaping Ghyll on Ingleborough, with its 340 ft shaft, miles of passages and huge main chamber On the evening of August 1, Sir Arthur Smith Woodward addressed the Association on Wild Animals Living with Early Man in Britain The Association will meet next year at Swansea

Roman Site in Wiltshire

An impressive indication of the general diffusion of a high degree of refinement in mode of life in Roman Britain and also of the economic and social decadence which accompanied the decay of Roman rule is afforded by the remains of a villa recently discovered at Atworth in Wiltshire (*The Times*, August 6) It is indeed remarkable that traces of a building of such an extent as has been revealed in the excavations of 1937 38 should have evaded previous record Its existence was made known only through the discovery by a schoolboy in a cornfield of a coin afterwards identified as of Constantine I This led to an investigation which was begun in August 1937 and at once revealed courses of masonry, in some instances no more than six inches below the ploughed surface now known to have been part of an L shaped house of corridor type containing at least twenty four rooms or passages a suite of baths, four or possibly five hypocaust chambers, a flight of six stone steps and three rather inferior tesselated floors Evidence that either on this site, or in the immediate neighbourhood there had stood a building of considerable architectural pretensions was found in the form of fragments of stone used to support a floor in one of the hypocausts, which were well worked and showed good mouldings They had once formed part of a cornice or plinth of a building in classic style The house was roofed with purplish pointed tiles of sandstone from the neighbourhood of Bristol Many rooms show evidence of conflagration in the form of a black deposit, mostly charcoal, above the floor, in which are broken tiles and roof nails In places three occupation levels can be seen, and sometimes the highest immediately above the burnt deposit is a primitive floor of rough flat stone or irregularly fitted pieces of roof tile Series of bronze coins range from Gallienus (A D 253–268) to Valens (A D 364–378), while the pottery can be ascribed to the second, third and fourth centuries A D It is thought that the villa may have been partially destroyed by fire in the raids of Picts, Scots, Franks and Saxons in A D 367, when many villas in south and western Britain were abandoned, to be occupied later, when the raiders had been driven out, by lower class Romano Britons

Prehistory and the Sahara

A meeting of the International Commission for Study of the Prehistory of the Sahara, which was initiated by Prof P Rivet, and of which Sir Robert

Mond is president, was held in Paris on June 27–30. It was attended by a number of distinguished archæologists and others interested in the problems of the Sahara from France, Great Britain, Egypt, Italy, Tunis, Morocco and the Sudan Numerous important communications, illustrated by lantern slides and exhibits, were presented and discussed in the sessions of the Commission. For the first time it was possible for the quaternary problem in the Sahara to be discussed as a whole, without reference to irrelevant political boundaries. Special stress, it would appear from a brief report in the *Journal des Débats* of July 4, was laid on the geological and geographical unity of the Sahara as a whole from the Nile to the Atlantic, in which the conditions of development, of desiccation, and of life are subject to the same general laws, notwithstanding certain local divergences. Valuable comparisons of observations from west, centre and east were made, and various conclusions emerged Among these, that from the early palæolithic onward it was not possible to establish exact correspondence between Africa and Europe, and secondly that the succession of the large number of rock engravings and paintings in the Sahara continued down to modern times The Commission, it will be seen, has thus made a substantial beginning in the important work of synthesis in Saharan studies. The results will appear in a volume, of which the publication has been guaranteed by Sir Robert Mond, who also entertained the members at luncheon at the close of the proceedings. It has been decided that the Commission will meet every fourth year, the business of the Commission in the interval being conducted by Mr. Harper Kelley at the Musée de l'Homme, Paris.

The Czechoslovak Research Council

DURING the twenty years of the existence of the Czechoslovak Republic, the university authorities and scientific institutions of that country have not failed to realize the importance of research work in the natural sciences Among the organizations which have fostered academic investigations is the Czechoslovak National Research Council (Československá Národní Rada Badatelská). This body has just issued its fourteenth annual report, in which reference is made to the work recently published and still in progress. Practically all branches of science are represented, and some of the investigations have been commented upon already in NATURE. From the report, too, it is learnt that several prominent Czechoslovak men of science have been invited abroad to describe their special contributions to recent advances in the different sciences. On the other hand, students from various European and American countries have spent some time in the laboratories at Prague and Brno, studying technique in chemistry (polarographic methods), archæology (excavations in Moravia), biology and physics. During the year under review the Council, together with other bodies, arranged for the International Congress for the History of Science which coincided with celebrations of the hundred and fiftieth anniversary of the birth of J. E. Purkyně, the physiologist. The report also refers to the support the National Research Council has given to some fifty students (fourteen of whom were thus able to go abroad), which has permitted certain investigations to be undertaken or prolonged. These include special geological surveys, archæological excavations, a study of certain properties of heavy water, work on genetics, the ecology of certain lake flora, and biochemical examinations of fungal colonies in beech woods.

The Rhodes Scholarships

THE Rhodes Scholarships statement for 1936–37 shows a distribution of the 185 scholars (93 from the British Empire overseas, 86 from the United States and 6 from Germany), as follows . natural science 56, philosophy, politics and economics ('Modern Greats') 36, law 29, modern history 17, English 14, Litt. Hum 10, economics 8, mathematics 6, modern languages 3, geography, education and colonial service probationers 2 each. The particulars given of distinctions achieved by former Rhodes scholars are interesting for the light they throw on the question how far the founder's objects are being realized. Every one of the fourteen Americans is described as holding an important position (such as head of, or professor in, a university or college, or member of congress) in America, which accords well with the words in Rhodes's will: "without, I hope, withdrawing them or their sympathies from the land of their adoption or birth". As regards the British Empire (the retention of the unity of which was one of the declared objects of the scholarships) noteworthy appointments mentioned are those of governor of the Canadian Broadcasting Company, solicitor to the Treasury, Ottawa, chancellor of the University of Sydney, director of education, Victoria, director of the Institute of Pathology, Sydney, and Nuffield professor of surgery, Oxford. One of the Germans is professor of economics and political science, University of Heidelberg, and another president of the Academy of Sciences, Munich. "The object", says the will, of the German scholarships, "is that an understanding between the three Great Powers will render war impossible and educational relations make the strongest tie".

Canadian Research Scholarships

FORTY-NINE scholarships have been awarded for 1938–39 by the National Research Council of Canada. Graduates from fourteen Canadian universities have been given awards which will enable them to pursue post-graduate studies at the following universities: Dalhousie, Laval, McGill, Montreal, Queen's, Saskatchewan and Toronto. Four special scholarships will be tenable in the National Research Laboratories at Ottawa, where the holders, who have already gained post-graduate experience in research, will be given an opportunity to put their talents to work on some practical problem such as they may expect to meet when they enter commercial or industrial work For work in the universities, the scholarships granted include one fellowship, seventeen studentships and twenty seven bursaries Twenty eight of the awards are to be used in financing graduate students in chemistry, including fourteen in physical chemistry, six in cellulose research, four in organic chemistry, two in general chemistry, one in inorganic chemistry and one on a practical chemical problem in the National Research Laboratories Twelve candidates will work in physics, including three in the National Research Laboratories Other divisions of science represented in the awards are biochemistry, 2, biology, 2, botany, 1, entomology, 1, genetics, 2, and mathematics, 1

Rockefeller Travelling Fellowships in Medicine

THE following Rockefeller travelling fellowships in medicine have been awarded by the Medical Research Council for the academic year 1938–39 R R Bomford, assistant physician, London Hospital, T Colver, outpatient medical registrar, Hospital for Sick Children, Great Ormond Street, London, R M Heggie, assistant lecturer in pathology and bacteriology, Welsh National School of Medicine, Cardiff, Ian MacKenzie, assistant surgeon, St Giles's Hospital, London, Dr G G E Smyth, Dickinson research scholar, National Hospital, Queen Square, London, Ivor G Williams, senior assistant radiotherapist, Meyerstein Institute of Radiotherapy, Middlesex Hospital All these fellows propose to work at centres in the United States, with the exception of Dr Smyth, who intends to study in Paris Dr Williams will hold his fellowship for six months only In addition, the Rockefeller Foundation has awarded similar fellowships, on the recommendation of the Medical Research Council, to the following candidates in the special field of psychiatry, neurology and related subjects, all of whom are from the Maudsley Hospital, London T R C Fraser, W W Sargant, and M J F McArdle

The World Power Conference

WE have received from the Central Office of the World Power Conference, Kingsway, London, the annual report for 1937 Dr William F Durand is the president and Sir Harold Hartley is the chairman of the International Executive Council The first conference was held in London in 1924, the second in Berlin in 1930 and the third in Washington in 1936 In addition, six other special meetings have been held The next meeting of the council will take place in Vienna on August 29, 1938 The total number of National Committees of the World Power Conference is now 42, and in addition there are four member countries with representatives After the conference at Vienna this year there will be a study tour of about a week's duration The Central Office continues to circulate to the National Committees and representatives, reports on the work being carried on by the International Special Committee on Radio Interference, under the auspices of the International Electrotechnical Commission

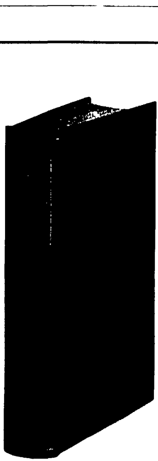
THE following appointments of official delegates to the sectional meeting of the World Power Conference to be held in Vienna on August 25–September 2, have been made to represent the Government of the United Kingdom, Sir Harold Hartley (chairman, International Executive Council and chairman, British National Committee of the World Power Conference, and Mr J M Kennedy, deputy chairman, Electricity Commission, appointed by the British National Committee of the World Power Conference, Sir Archibald Page, chairman, Central Electricity Board, and Dr F S Sinnatt, director of fuel research, Department of Scientific and Industrial Research The total attendance from the United Kingdom will exceed eighty, which is a record for any sectional meeting of the World Power Conference held abroad

International Management Congress

STRONG British support has been secured for the seventh International Management Congress which meets in Washington, D C, on September 19–24 More than ninety delegates fully representative of British industry, are attending to support Lord Leverhulme, who is the president of the International Committee An interesting unit of this party consists of nine young executives, one of whom is a lady, who are being assisted by bursaries paid out of the funds remaining from the sixth International Congress held in 1935 in London This party will travel together as a unit under the leadership of Dr E F Armstrong it is anticipated that each will profit from the collective experience of the whole Four tours by motor coach have been organized, enabling the delegates to visit a number of factories and cities Before the Congress, there is one tour of six days in New England and a second, taking five days, to the highly industrialized country between New York and Washington After the Congress, an eleven day tour goes through the mid-West to Chicago and back to New York via Buffalo and Niagara, and there is a final short tour to Boston It is proposed to give some form of written report of the visits, which will serve as a permanent record The tours are likely to be of exceptional educational value from the point of view of scientific management About 250 papers from some twenty countries have been accepted by the Congress The papers of each technical section have been summarized The chairman of the Congress Council is Mr Willis H Booth, vice president of the Guaranty Trust Company, that of the Co ordinating Committee is Mr William L Batt, president of S K F Industries, whilst the chairman of the Organizing Committee is Mr Harry A Hopf, well known as one of the most active protagonists of the management movement The delegates will be welcomed by Mr Cordell Hull, and there will be a formal reception at the White House

International Scientific Radio Union

THE sixth General Assembly of the International Scientific Radio Union (Union Radio Scientifique Internationale) will be held in Italy on September 4–14 The U R S I is one of the constituent bodies



NEW theories and the results of recent researches necessitated a thorough revision of this standard text. Every chapter has had a general revision, but the most extensive changes have been made in connexion with excitation, contraction, chemical transmission, structure of membranes, the permeability of cells, physiological oxidations, the chemistry of muscle, the vitamins, and the hormones. Entirely new sections have been added on the organizers or evocators, oxidation-reduction potentials, Liesegang phenomena, and the physiological study of temperature characteristics.

As in the earlier editions, the selection of material is based upon a desire to present those aspects of the subject which are most useful to the student who takes but one college course in physiology With this in mind, digestion is studied in man rather than in the amoeba : a considerable amount of mammalian physiology is included · and illustrations of general physiological principles are chosen, wherever possible, from mammalian work

Since the majority of undergraduates who study general physiology are not equipped in physical chemistry and biochemistry, the chapters dealing with these two subjects have been retained in the revision

Many new illustrations have been added to the third edition of TEXTBOOK OF GENERAL PHYSIOLOGY, and the bibliographies have been considerably enlarged.

A new LABORATORY MANUAL FOR GENERAL PHYSIOLOGY by Professors Mitchell and Taylor is available (price 8 6 net) for use in conjunction with the text.

Textbook of General Physiology

By PHILIP H. MITCHELL

Robert P. Brown, Professor of Biology, Brown University

853 pages, 9 × 6, 200 illustrations, Third Edition, 36/- net

NEW AMERICAN BOOKS

General Psychology

From the Personalistic Standpoint

By WILLIAM STERN

Professor of Psychology, Duke University, U.S.A.

Translated by **H. D. Spoerl,** Director, Department of Psychology, American International College.

Deals with numerous particular facts of human experience by presenting the "psychology" of such experience in terms of, and from the point of view of, the individual person. 20*s*. *net.*

An Introduction to the Social Studies

An Elementary Textbook for Professional and Preparatory Groups

By JOSEPH K. HART, Ph.D.

A preliminary survey of the social world, intended to give assistance to those young people who in the future, as doctors, nurses, lawyers, ministers, teachers, engineers, etc., will be "engaged in either strengthening or weakening the foundations of society." 8*s*. 6*d*. *net.*

High School Biology

By R. C. BENEDICT

Professor of Biology in Brooklyn College

W. W. KNOX

Acting Director, Division of Inspection and Examinations in the New York State Department of Education

and G. K. STONE

Instructor in Biology, Junior-Senior High School, Hicksville, Long Island

"Planned for large groups of Secondary School pupils of 'average ability', with the idea of linking the subject up with daily life."—*Times Educational Supplement.* 8*s*. 6*d*.

The Kelley Statistical Tables

By T. L. KELLEY, Ph.D.

Professor of Education, Harvard University, U.S.A.

Carefully prepared reference tables for those engaged in statistical work in the fields of education, psychology, economics, or any of the various sciences. 20*s*. *net.*

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD ST ALBANS

of the International Council of Scientific Unions, with its secretariat in Brussels; and it is concerned with the various scientific aspects of radio communication and radio physics, in many branches of which international discussion and co-operation is beneficial in stimulating both theoretical and experimental research. At the previous general assembly of the U.R.S.I. held in London in 1934, Prof. E. V. Appleton was elected president, and he is also chairman of the British National Committee, of which Dr. E. H. Rayner is secretary. Other members of this committee who will be attending the forthcoming meeting in Italy include Prof. S. Chapman, Mr. T. E. Eckersley, Mr. E. B. Moullin, Mr. J. A. Ratcliffe, Dr. R. L. Smith-Rose and Mr. R. A. Watson Watt. It is anticipated that representatives of some twelve or more other nations will also be in attendance. The work of the General Assembly is divided among five commissions dealing respectively with radio measurements and standards, the propagation of waves, atmospherics, liaison and radio physics. The opening meeting will take place on September 4 at Venice, where most of the business of the Assembly will be carried out during the ensuing week. The formal closing meeting takes place in Rome, and various technical visits and other appropriate engagements of interest are included in the programme.

Imperial Veterinary Conference

An Imperial Veterinary Conference will be held at the Royal Veterinary College, Camden Town, London, N.W.1, on August 15–19. The subjects to be discussed will include the work of the Imperial Bureau of Animal Health, foot-and-mouth disease and certain other virus diseases, Johne's disease, bovine mastitis, caseous lymphadenitis of sheep, sheep blowflies, fowl paralysis and chronic bovine hæmaturia.

Announcements

The Jenner Medal of the Royal Society of Medicine, which is awarded for distinguished work in epidemiological research or for pre-eminence in the prevention and control of epidemic disease, was presented to Sir Arthur Newsholme on July 19.

The *Queen Mary* has established a new record for the east to west crossing of the Atlantic. She berthed at New York on August 8, after having covered the distance from the Bishop Rock to the Ambrose Channel lightship in 3 days 21 hours 48 minutes, at an average speed of 30·99 knots.

It is announced by the Berlin correspondent of *The Times* that a new height record for a glider was set up at Wasserkuppe by Capt. Walther Drechsel on August 5, when he ascended to 23,190 ft. The machine, a Minimoa glider, was towed to a height of about 3000 ft. and then released.

Through the generosity of the late Mr. Herbert Harlow of Bradford, the Bradford Technical College has been able to establish a Harlow fellowship of the value of £250 a year for research to be carried out at the Technical College, Bradford, in one of the branches of science relating to the textile industry or the dyeing industry. Mr. R. Williamson has been appointed to the first fellowship.

An Advisory Committee on Blindness, including its prevention and treatment, has recently been formed by the Minister of Health. The following have been appointed members of the Committee: Dr. P. M. Evans (chairman), H. R. Bickerton, J. D. Magor Cardell, Miss Grace Cracknall, James Ferguson, Percy Fleming, N. Bishop Harman, Dr. E. K. Macdonald, Miss Ida Mann, R. Foster Moore, G. F. Mowatt, Sir John Parsons and A. H. H. Sinclair. The Committee has been appointed for a period of three years. Mr. H. G. Benjamin, of the Ministry of Health, will be secretary, and Dr. A. E. Hallinan, of the Ministry of Health, will be medical secretary of the Committee.

The following awards for 1938–39 have been made by the Salters' Institute of Industrial Chemistry and approved by the Court of the Salters' Company. Fellowships have been renewed in the case of Messrs. A. J. Shorter (to the University of Illinois), J. L. Tuck (at the University of Oxford) and to S. H. Wade (at Imperial College, London). Fellowships have been awarded to H. D. Anderson (University of Oxford), A. Cameron (Imperial College, London), H. S. Corran (University of Cambridge) and R. N. Haward (University of Cambridge). The Salters' Institute has also awarded fifty grants-in-aid to young men employed in chemical works in or near London to assist them in their studies.

The following appointments and promotion have been made in the Colonial Service: H. C. Thorpe to be plant breeder, Kenya; M. H. C. Glyn, to be veterinary officer, Northern Rhodesia; W. G. G. Pevie, to be veterinary officer, Tanganyika Territory; D. A. Frye, to be assistant analyst, Analyst's Department, Straits Settlements; J. R. E. Hindson (agricultural superintendent, Gold Coast), to be agricultural officer, Northern Rhodesia; R. M. Nattrass (plant pathologist, Cyprus), to be senior plant pathologist, Kenya; Gunn Lay Teik (assistant analyst), to be chemist, Department of Agriculture, Federated Malay States; W. Molegode (officer of Class I, Grade I, Agricultural Department), to be agricultural officer (Propaganda), Ceylon.

Dr. Wendell Meredith Stanley, of the Rockefeller Institute, Princeton, has been awarded the Rosenberger Medal of the University of Chicago in recognition of his isolation of crystalline forms of the filtrable viruses. The Rosenberger Medal for distinguished achievement in the advancement of learning or for notably great service in the promotion of human welfare has been awarded five times previously.

The first International Congress for Forensic and Social Medicine will be held at Bonn on September 22–24 under the presidency of Prof. Pietrusky, director of the Bonn Institute of Forensic Medicine. Further information can be obtained from Prof. Schrader, Franzosenweg 1, Halle a.d.S.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 296.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Fundamental Physical Concepts

THE flux-cutting equations, $H' = [VJ] = \varepsilon[VE]$ and $E' = -[VB] = -\mu[VH]$, enunciated in my article in NATURE of February 5, in conjunction with the ionic constitution of matter and the simple physical treatment of electric wave propagation, have suggested some novel physical concepts which may help towards at least a partial reconciliation between the classical and modern theories.

The classical theory was based on macroscopic experiments and hence dealt almost exclusively with average or resultant forces and fields; but if an attractive force or bond exists between every proton and electron, these straight bonds constitute the actual lines of force, and our familiar 'lines of force' are really only imaginary lines which indicate the direction of the resultant force and have no physical existence. An 'uncharged' body, that is, one containing equal numbers of protons and electrons, certainly produces no external resultant field, but on this view it has two similar systems of bonds radiating from its protons and electrons respectively, so that it should be regarded as being surrounded by two equal and opposite electric fields, and since an electric current consists of a procession or stream of electrons or protons or of both travelling in opposite senses, a linear current must be surrounded by two opposed radial electric fields moving translationally past each other. Since $H = [VJ] = jVJ \sin\theta$, and $J = e/r^2$ at a distance r from a charge e, $H = jev \sin\theta/r^2 = jids \sin\theta/r^2$, so that these moving electric fields are equivalent to a magnetic field and no vertical concept of a magnetic field appears to be called for.

The attractive force or tension in the bond between a proton and electron of charge $\pm e$ respectively is of course $T = e^2/\varepsilon r^2$, and the electrokinetic or 'magnetic' energy of a transversely moving electric field shows that the bond has an equivalent mass of $m = \mu e^2/r^2$ per unit length. But the velocity of propagation of transverse disturbances along a cord under a tension T and having a mass m per unit length is $V = \sqrt{\frac{T}{m}}$, so that for the above values of T and m, V should be $1/\sqrt{\varepsilon\mu}$. This indicates that transverse electric disturbances travel along the bonds exactly as if these bonds were material fibres or contractile tentacular projections from the protons and electrons, and enables the field distribution round a dipole oscillator to be determined with great simplicity. Incidentally, the total mass of the bonds surrounding a spherical charge e of radius r_0 works out to Sir Joseph Thomson's value of $2\mu e^2/3r_0$ for the electromagnetic mass associated with the charge.

In dielectric media the bonds between the molecules are loaded with ions which are also cross-coupled by the intra-molecular bonds, and the passage of an electric disturbance produces transverse displacements of the positive and negative ions in opposite senses, which are opposed by the inter- and intra-molecular bonds. This modifies the velocity of propagation and makes it dependent on the wavelength, in accordance with the Drude dispersion theory. If the medium moves, its internal bonds which correspond to Fresnel's 'bound ether' move with it, while the bonds which connect external charges and correspond to his 'free ether' do not, and this provides a simple explanation of the Fresnel drag coefficient.

Although this material bond hypothesis offers no explanation of the repulsion between like charges, except the pressure which must result from the attractive forces, it provides a very simple picture of the processes involved in electric wave propagation which is in complete agreement with the Maxwellian theory; and since the bonds appear to have mass they may be slightly curved or deflected by transverse gravitational as well as by electric fields, which may explain the deflection of light passing near the sun, and gives a simple physical interpretation of the relativistic 'curvature of space'. Moreover, although the bonds from a single orbital electron must oscillate and transmit radiation, those from a close assembly of such electrons will evidently interfere and transmit little or no radiation; while sporadic and more widely separated disturbances caused by changes of orbit would be transmitted with little interference. This conforms, at least qualitatively, with the Quantum theory; and if we assume that the violent ejection of electrons is accompanied by high frequency oscillations of their shape and bonds, the Heisenberg wave electron and electron diffraction phenomena become physically intelligible.

One other point of fundamental importance arises from the flux-cutting principle. The basic feature of wave propagation is that the displacing force due to acceleration balances the elastic controlling force. For a stretched cord transmitting a deformation of radius R, the displacing force is mV^2/R, which we can write down directly; but for electric waves we have to derive it by two stages $H' = j\varepsilon VE$ and $E' = -j\mu VH' = \varepsilon\mu V^2 E$, that is, by reciprocal electric and magnetic induction. But Ampère's experiments on the forces on current-carrying conductors gave us $f = \mu \frac{ids\, i'ds'}{r^2} \sin\theta$ for the transverse force on either of two parallel current elements ids and $i'ds'$ separated by a distance r and making an angle θ with r. Hence if we have two charges e and e' moving with velocity V transverse to r, $f = \mu ee'V^2/r^2 = \varepsilon\mu V^2 Ee'$, since $E = -e/\varepsilon r^2$, without any magnetic considerations. In conjunction with the above concept of a magnetic field as a translationally moving electric field, this suggests that 'magnetic force' should be regarded fundamentally as simply a symbol for $4\pi[VD] = [VJ]$, that magnetism may with advantage be eliminated from all fundamental physical discussions, and that it may be possible to express the forces associated with protons and electrons at rest and in uniform and accelerated motion by a single comprehensive formula, thus eliminating both the curl- and flux-cutting equations Such a change would be a great help towards clarifying fundamental problems, but it will take some time to formulate and assimilate, and in the meantime the flux-cutting equations and the simple physical concepts to which they lead should greatly facilitate the teaching and application of the Maxwellian theory.

Radio Fadeouts, Auroras and Magnetic Storms

FROM observations made in the South Island of New Zealand we may add to the data already published in NATURE on the connexion between the radio fadeouts, auroras and magnetic storms of the two periods January 20–22 and January 24–26, 1937

As reported from Canberra[1], the first of these periods of activity began with solar activity and poor reflection of wireless waves from the ionosphere The wireless observations in New Zealand do not correspond exactly with those of Canberra On beginning observations of the reflection of waves from the F_2 region at 2100 G.M.T. on January 20 no reflected wave could be observed and this fadeout lasted until 2305 hours, after which time weak echoes were obtained

Magnetic conditions were moderately stormy during January 20 and 21 and an aurora was observed over New Zealand with its maximum phase at 0945 hours G.M.T., January 21. This faded out at 1100 hours. The magnetic storminess culminated in a major storm beginning at 0240 G.M T., January 22 and during the entire night an intense auroral display occurred in the southern hemisphere with its maximum phase at 1045 G.M T., January 22, when it was seen in Canberra

The interval from 2100 hours January 20, when the radio fadeout was first observed, until 0240 hours January 22, when the magnetic storm began, is about 30 hours.

The intense aurora which accompanied the storm probably began during daylight, since complex echoes from the ionosphere which accompany such activity were observed.

On January 24 the Christchurch observations of the radio fadeout corresponded exactly to those made at Canberra An interesting feature of the following period not already reported is that a good auroral display began in the southern hemisphere about the time of commencement of the magnetic storm at 1150 G.M.T., January 25. Through cloudiness it was not seen until 1315 G.M.T., but from the stage of development at that time it had probably started earlier.

This was in all probability the beginning of a period of world-wide auroral activity. The southern aurora mentioned above was followed by the intense aurora in the northern hemisphere[2] from 1800 G.M.T , January 25, until about 0230 G.M.T., January 26. This in turn was followed by another southern aurora observed in the evening from about 0900 h. G.M T., January 26 It seems reasonable to assume that an intense daylight aurora may have been in progress in the southern hemisphere at the same time as that observed in the northern hemisphere, for during the whole period of ionospheric observations in Christchurch from 2100 hours, January 25, until 0530 hours, January 26, no echoes could be received from the ionosphere. The magnetic storm was in progress during most of this period

The above auroral observations show that the estimated time interval of 39½ hours from the solar eruption (at 0250 G M T , January 24) to the commencement of the aurora is too large, but that this interval should be about the same as that to the commencement of the magnetic storm, i e., approximately 33 hours

Ionospheric conditions in Christchurch appear to be similar to those observed at Tromsø by Appleton[3] during a magnetic storm and auroral display. It is found, for example, that 'no echo' periods often occur in the morning following a night of magnetic and auroral activity The fadeout at 2100 G.M.T., January 20, may be of this type although no auroral or magnetic activity is known to have preceded it. Radio fadeouts coinciding in time with solar eruptions are observed as well as the periods of 'no echo' mentioned above It would appear, therefore, that in high latitudes a radio fadeout may be due to ultra-violet radiation emitted during an eruption or may also be due to ionization by the particle radiation causing the auroras

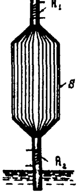
Further Experiments on Liquid Helium II

IN a previous note[1], we reported our investigation of the formation of a thin film of liquid helium II on the walls of a tube which is in contact with it A very rough estimation of the thickness of the film was made from the amount of heat necessary for its destruction , it was found to be of the order 10^{-6} cm. The object of the further research was a direct determination of the thickness of the film



The apparatus for the measurements is shown in the accompanying diagram Here S is a cylinder of a great area, on the upper and lower part of which are soldered two tubes 4 mm. in diameter. A resistance thermometer R_1 of phosphor bronze wire 0 051 mm. thick is wound on the upper tube ; a heating coil R_2 of constantan wire 0·1 mm. thick is wound on the lower tube. The lower part of the apparatus is immersed in liquid helium so that the heating coil is above the level of the liquid. In the presence of a film of liquid helium II on the surface S, the thermometer R_1 indicates the temperature of the liquid helium II in the lower part of the apparatus On switching on in the heating coil a current above the critical value[1], the film disrupts and the thermometer registers a rise of temperature in the upper part of the apparatus This rise of temperature amounted to about 1° No temperature rise occurred at currents below the critical value

The procedure is as follows The presence of the film is ascertained from the readings of the thermometer R_1 The current in the heating coil is then switched on whereupon the film is disrupted With current on the dropping of the level of helium caused by evaporation is observed by means of a cathetometer After a while the current is switched off and, consequently, the film is allowed to form again

The curve of the dropping of the level as a function of time is taken throughout the experiment This curve exhibits a break and a jump at the moment the current is switched off From the magnitude of this jump, the surface of helium in the Dewar vessel and the surface S one easily finds the thickness of the film

Three experiments were carried out with different areas of S namely $700\ \mathrm{cm}^2$, $2\ 800\ \mathrm{cm}^2$ and $10\ \mathrm{cm}^2$ In the first two cases the jumps were $1\ 5 \times 10^{3}$, and $3\ 5 \times 10^{3}$ cm respectively as was expected no jump occurred in the third case Taking into account the quantity of helium evaporating during the cooling of the apparatus heated by 1° by the heating coil, we find from this data the thickness of the film to be 2 to 3×10^{-6} cm It should be noted that the film is easily destroyed even by faint illumination Therefore the experiments were carried out in a dark room and very faint light was used for observing the level

Knowing the thickness of the film it is possible to draw some conclusions on the thermal conductivity and the viscosity of liquid helium II (so far as thin films are concerned)

(1) Our experiments show that the transfer of heat even in a thin film is high It is not likely to depend on convection, as the film is very thin It may be, however that the equalization of the temperature is merely due to the presence of the film and permanent evaporation of it

(2) From the recent experiments of J G Daunt and K Mendelssohn[2], who have determined the rate of transfer of liquid helium II on the surface of a solid in contact with it (an experiment analogous to that of these authors has been performed by us) one can, knowing the thickness of the film estimate the viscosity of liquid helium therein It proves to be much higher than the viscosity of liquid helium II, measured by P Kapitza[3] Of course our experiments refer to thin films only

A detailed description of our experiments will be published in one of the Russian physical journals

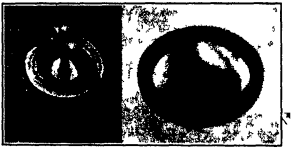
Motion of a Spinning Top

IF a gyroscope is made with a heavy frame having a mass equal to or greater than the mass of the disk, then when the disk is set in rapid rotation about a vertical axis and the frame (provided with a supporting point) placed upon a smooth surface (Fig 1a), the friction between the axle and the frame will soon set the frame in rapid rotation In order to produce the proper amount of friction the tightness of the axle in the frame is variable by means of an adjustable lock nut As the frame rotates about the vertical axis it will take on a precessional rotation because of the pull of gravity This precession gradually increases so that at the right moment the frame is rotating partially about an axis perpendicular to its plane This angular velocity tends by centrifugal force to throw the frame into a position in which its plane is horizontal This change takes place very suddenly so that the top flipping violently from one axis to another at right angles continues to rotate about the second axis The initial and final position are shown in the photograph



(a) (b)

Fig 1

For best results the top should be rotated at high speed with an electric spinner The friction between the axle and the frame must be exactly right It is better to place the top upon a smooth metal plate, since then the frame can take up its rotation quickly without loss of energy to the supporting surface The top should be designed to withstand high rotation speeds It should not be touched after it is spinning on the plate since the tipping over is sudden and energetic

The Theory of Nuclear Forces

ACCORDING to the theory proposed by Yukawa[1] the neutron proton interaction is due to the exchange of a particle having the elementary charge either positive or negative and a mass $m = \frac{h\varkappa}{c}$, where h and c are Plancks constant and the velocity of light and $\frac{1}{\varkappa}$ is the range of nuclear forces The proper description of these new particles, which have spin equal to one and obey Bose statistics, is obtained by quantization of the equations of Proca[2] Introducing a *complex* four vector with components U^{μ} ($\mu = 1, 2, 3, 4$) and a *complex* antisymmetrical world tensor with components $\chi^{\mu\nu}$ ($\mu, \nu = 1, 2, 3, 4$) these equations can be written

$$(1) \quad \begin{cases} \sum_{\nu=1}^{4} \dfrac{\partial \chi^{\mu\nu}}{\partial x^{\nu}} + \varkappa^{2}\, U^{\mu} = 0 \quad (\mu = 1, 2, 3, 4) \\ \chi^{\mu\nu} = \dfrac{\partial U^{\nu}}{\partial x_{\mu}} - \dfrac{\partial U_{\mu}}{\partial x_{\nu}} \end{cases}$$

where $(x^{\mu}) = (x, y, z, ct)$ are the space-time co-ordinates and $\varkappa$ is the universal constant determining the range of the forces Similar equations hold for the conjugate complex quantities $\widetilde{U}^{\mu}$ and $\widetilde{\chi}^{\mu\nu}$

The charge and current densities connected with the new particles are given by the components of the four vector

$$(2) \quad S^{\mu} = e\, i \sum_{\nu=1}^{4} (\widetilde{\chi}^{\mu\nu} U_{\nu} - \widetilde{U}_{\nu} \chi^{\mu\nu}) \quad (\mu = 1, 2, 3, 4),$$

which vanish only if the real and imaginary part of the field quantities have a constant ratio and in general represent particles of either positive or negative charge

It has already been pointed out by several authors[3] that it might be necessary to introduce neutral particles also to account for the big forces between two neutrons and between two protons, and the question has been discussed what kind of field equations are suited for the representation of such particles The only simple equations, however, which have the right spin properties and always give positive values for the energy are those of Proca, and it may therefore be of interest to remark that the solutions of (1) where the real and imaginary parts are not independent of each other and which accordingly give no contribution to the charge and current densities in (2) will just seem to be suited to represent such fields

In that case it is, of course, only necessary to consider *real* field quantities U^{μ} and $\chi^{\mu\nu}$ and the representation of the nuclear fields shows, therefore, a striking resemblance to the ordinary electromagnetic theory from which the equations (1) only differ by the terms containing the universal constant $\varkappa$ Accordingly, the quantization of these equations can be performed exactly as in quantum electrodynamics, that is, the radiation field can be treated as an infinite number of harmonic oscillators or as an assembly of quanta As regards energy and momentum these quanta will behave like material particles with rest-mass $m = \dfrac{\hbar\varkappa}{c}$ but, as in the case of photons, it is impossible to define a density in ordinary space of the heavy quanta, the particle properties of which result only from the quantization

From this point of view the field theory based on the equations (1) offer possibilities of accounting for forces between like and unlike nuclear particles of a more general character than hitherto recognized These consequences will be discussed in detail in collaboration with L. Rosenfeld in a forthcoming paper to be published in the *Proceedings of the Copenhagen Academy*.

Spectrum of Rubidium Hydride, RbH

A BAND spectrum of the many-line type has been obtained from a discharge through a mixture of rubidium vapour and hydrogen The discharge tube with a constriction in the positive column which was originally designed for the production of the manganese hydride spectrum[1] was found to be an intense and economical source, the spectrum has been photographed on a 20-ft concave grating spectrograph with exposures ranging from 10 to 40 minutes.

The spectrum, which extends from 4800 A to 6500 A, is very similar to the already known spectra of the diatomic hydrides of the alkali metals, the bands being due to a $^1\Sigma \rightarrow {}^1\Sigma$ transition and being strongly degraded to the red, so that the heads are poorly developed and have only been observed for some of the strongest bands So far, nineteen bands have been classified, and a preliminary analysis leads to the following approximate values of the molecular constants·

$\nu_e = 18912$ cm^{-1} $\qquad \nu_0 = 18573$ cm^{-1}
$\omega_e' = 248$ $\qquad \omega_e'' = 934$

The large difference between ω_e'' and ω_e' produces some uncertainty in the assignment of the values of v', and the values given below may have to be raised by one or possibly two units The vibrational energy terms of the upper electronic state, like those for the hydrides of the other alkali metals, are anomalous in having a negative value of $\omega_e' x_e'$

The following are the approximate positions of the heads of the strongest bands,

λ	v', v''	λ	v', v''
6277	0,3	5345	4,1
6178	1,3	5267	5,1
5871	1,2	5027	5,0
5782	2,2	4958	6,0
5694	3,2	4891	7,0
5422	3,1	4826	8,0

The investigations are being continued, and a rotational analysis is in progress
